SUPPLEMENT TO "THE ELECTRICIAN," MAY 4, 1894.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

UNIVERSITY OF
LIBRARY

VOLUME XXXII.

FROM NOVEMBER 3, 1893, TO APRIL 27, 1894.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1894.

UNIVERSITY OF ILLINOIS LIBRARY

INDEX TO "THE ELECTRICIAN."

VOL. XXXII.

General Alphabetical Index.

[illegible] figures denote that the subject matter is in the "LEADING ARTICLES" or in the "EDITORIAL NOTES."

A

[illegible]-ABAKANOWICZ, B.:
Compensation for Hysteresis, 93
[illegible] des Sciences Prizes, 210
[illegible] 3, 54, (*Glasgow*) 83, 210, (*Ludgate Hill and* [illegible]) 261, 313, *404*, 406, 412, (*Blackfriars*) *285*, [illegible]) 341, 377, (*Innsbruck*) 655
[illegible] Synchronisers for Alternators, 342
[illegible] and Reaction, *209*. (*See also pages* 200, 224).
[illegible] Solutions, Voltage of Decomposition, Thermo-[illegible] Calculation of, *514*
[illegible] Self-Contained Condensing Plant, 381
[illegible]-Current Circuits, Claude Safety Device for, [illegible]
[illegible]-Current Electrolysis, 139
[illegible]-Current Phasemeter, 40
[illegible]-Current System, The Scott, 590, *623*, 640
[illegible]-Current Waves, The Dying-out of, 235
[illegible]-Currents, A Potentiometer for: by J. Swin-[illegible] 163
[illegible] Currents, Resistance to: by E. Hospitalier,
[illegible] Volts, Fall of, on Long Lines, *233*, 239

Alternators—
[illegible] Synchroniser, 342
[illegible] of, by Gas Engines: by J. Emerson [illegible] (*See also page* 429)
[illegible] de l'Industrie Electrique, 519
[illegible]-Branton, 168
[illegible] Working, 55
[illegible] Working, with Special Reference to Long [illegible] by W. M. Mordey, 554, 582, *643*, 644
[illegible] 10,000-Light Machine, 313

[illegible] 341
[illegible] Electrical Engineering and its Lessons, *64*
[illegible] Institute of Electrical Engineers, 124, *209*, 624
[illegible] Rule, 69
[illegible] Gas Retort Carbon, 406
[illegible] in Journalism, 551. (*See also page 550*)

Arc Lamps—
Arc Lamp Design: by Wm. A. Turbayne, 139. (*See also page 132*)
Arc Lamps on Alternate-Current Circuits, 592
Davenport Lamp for Optical Lanterns, 393
[illegible] Lamp for Optical Lanterns, 520
Hansen Lamp, 167
Inverted Arcs, 13, 133
Rating of Arc Lamps, 590
Small Arc Lamps, 601, 656

[illegible] Standard of Light, The, *164*
[illegible], The Alternating-Current: by André Blondel, 161
[illegible], The Alternate-Current, Physics of, 544
[illegible] Stampings, Insulation of, *441*
[illegible] Cables for Distributors, *541*
[illegible], RICCARDO:
Dissipation of Energy in Dielectrics placed in a Rotating Electric Field, 222
[illegible], W.:
Glasgow Corporation Electric Supply, 727
[illegible] Electricity, 263
[illegible]-Canadian Cable, The Projected, 81
[illegible], Electric, 30
[illegible], Prof. W. E.:
An Astatic Station Voltmeter, 688
A Universal Shunt Box for Galvanometers, 627. (*Discussion*) 639, 635
Best Resistance for the Receiving Instrument on a Leaky Telegraph Line, 692
[illegible] Conducting Screens for Electric and [illegible] Apparatus, 693

B

[illegible] H.M.S., Electric Motors on, 601

Batteries (Primary)—
[illegible] Batteries in Theory and Practice: by W. [illegible], 7

Batteries (Secondary)—
[illegible]-Electrical Storage Battery, The; by Herbert [illegible], 45
[illegible] Patent in Germany, 188

Batteries (Secondary), *Continued*—
Fire in an Accumulator House, 515
Home Office and Accumulator Works, 157, 188, 262
Storage Batteries in Telegraph Work, 236
Storage Battery Outlook in America, 72
Verdier Accumulator, 170
Waddell-Entz Patents, 182

BARR, J. M., and PHILLIPS, E. S.:
The Brightness of Light: Its Nature and Measurement, 524
Beaumont, W. W. On the Automatic Balance of Machinery and Prevention of Vibration, *475*
BEDELL, FREDERICK:
Hedgehog Transformer and Condensers, 15
Belt-Driving *v.* Direct-Driving and other Controversies, *352*
Belts, Preservation of, 359
Bimetallic Dynamo Company, 210
Bimetallic Wire, 377, 443
Birkeland and Sarasin on the Reflection of Electromagnetic Waves, 144
BLAKESLEY, T. H.:
Note on a New Electrical Theorem, 388
Bleaching by Electricity, 108
BLONDEL, ANDRE:
Alternating-Current Arc, The, 161
Continuous Current Arc as a Standard of Light, The, 117, 145, 169. (*See also page 164*)
BLOUNT, BERTRAM:
Electrical Concentration of Vitriol, 34, 240
Electrolysis of Salts of the Alkali Metals, 381
Blow-pipe, The Warren Electro-Chemical, *375*
Board of Trade and Municipal Electric Lighting, *654*
Board of Trade Electrical Standards Committee, 479
Board of Trade Traction Regulations, 83, 96, *116*, *234*, *380* (*Tramways Institute*) 327, (*Conference at Board of Trade*) *339*, *441*, 477, *490*, 493, (*Objections to Regulations*) 458, (*Final*) 577, (*Draft for Railways*) 579
Boiler Incrustation, 264, 443
Boilers, The Care of, 32
Boilers, Water Tube, 607
Bolometer, The, 601
Boy-Messenger Service and the Post Office, *707*
BOYS, Prof. C. V.:
On the Attachment of Quartz Fibres, 488
Bowden Cable Coupling, 40
"Brandenburg" Accident and the Daily Press, *515*
Brighton and Hove Company, *261*, *286*, 303, 330
British Association, 478, *570*
BRUCCHIETTI, G.:
Resistance and Thermo-Electric Power of Hydrogenated Palladium, 91
"Brush" Switches and Switching Gear, 457
Brush, Woven Wire and Graphite, 600
Buoy Lighting at the Chicago Exhibition, *570*

C

Cable Coupling, The Bowden, 40
Calculus, The Principles of the, 33, 134
CAMPBELL, ALBERT:
Electrical Units, 410
Cambridge, (*Research Scholarship*) 210, (*Engineering at*) 31, 212, (*Cavendish Laboratory*) 376
Canals, Electricity on, 109, 184, 263
Canada, History of the Telephone in: by L. B. M'Farlane, 360
Candle Flames, *570*, 571
Candle, Standard, Definition of, *181*
Candles *v.* Electricity on Coastguard Ships, 323
Car Accidents, 3
Carbon, Combustion of, 342
Carbons for Electrical Use, 114, 132, 133, 211
CARTER, E. TREMLETT:
Motive Power and Gearing, 111, 135, 159, 213, 237, 289, 313, 379, 408, 545, 664, 712
Energy, Storage of, 237
Economic Law of Design, 160
Fuels, 343, 379
Heat, Physical Effects of, 408
Introductory, 111, 135
Load, Load Diagrams, and Load Factors, 159
Powers and Work Measurements, 213
Steam and Water, 664, 712
Thermodynamics, 545
Cathode Rays: by Prof. G. F. Fitzgerald, 573; by P. Lenard, 514, 613, 630: by H. Hertz, 722; by Prof. Oliver Lodge, 722

Caustic Soda and Bleach, Electrolytic, *442*
Central Station, Proposed Floating, 515
Central Station Lighting and High-Priced Coal, *29*
Central Stations and their Customers, *312*
Central Stations in Germany, 263
Central Stations of the United Kingdom, *233*
Central Stations, Provincial, of France, 342
"Centurion," H.M.S., Electric Motors on 263
Charging, Systems of, (*Edinburgh*) 515, (*Bristol*) *541*
Chatsworth, Electric Lighting at, 223
Chemical Change, Conditions of, 412
Chemical Change, Transformation of Mechanical Force into, 626
Chemical Interchanges, 183
Chemistry, Institute of, (*New Laboratories*) 157
Chicago Congress, India and the, 571
Chicago, Notes on a Trip to: by W. H. Preece, 354, 389
City and Guilds of London Institute (*Annual Report*) 9
City of London, Some Notes on the Electric Lighting of: by Major-Gen. C. E. Webber, 423, 447, 482, (*Discussion*) 487
Civil Engineers, Institution of, (*Papers invited*) 32, (*Honorary Members*) 183, (*Education of Students*) 444, 515
CLAUDE, G.:
Central Stations and New Transformers, 90
On the Means of Increasing the Safety of High-Pressure Alternate-Current Distributions, 297
CLIREHUGH, S. V.:
Various Systems of Underground Mains and Methods of Laying Same, 553. (*Discussion*) 585, 696
Coal and "Coal," *608*
Coast Defence and Electric Light, 377
Coke, The Sweating of, 626
Cologne Central Station, The: by C. P. Feldmann, 187. (*See also pages 182, 209, 215*)
Combustion of Carbon, 342
Commutation in Motors and Dynamos: by J. A. Kingdon, 137

COMPANIES' MEETINGS, REPORTS, DIVIDENDS, STATUTORY RETURNS, &c.

(Abbreviations:—Mtg., Meetings of Shareholders; Rpt., Reports of Directors; Div., Dividend; Rev., Revenue; Stat., Statutory Returns.)

African Direct Telegraph Company—207, 739
Akester Electric Syndicate—Stat., 511
Aladdin Primary Electric Battery Company—Stat., 105
Alldays and Onions—51
Allgemeine Elektricitats-Gesellschaft—Rpt., 81.
Altrincham Electric Supply—650
Aluminium Company—Rpt., 27; Mtg., 24, 179
Anders Telephone Company—309; Stat., 739
Anglo-American Telegraph Company—Rpt., 306; Mtg., 369; Div., 679
Anglo-Portuguese Telephone Company—Mtg., 621; Stat., 739
Ariel Company—105; Stat., 259
Aurora Electric Lighting and Distribution Company—Stat., 105
Babcock and Wilcox—Div., 489
Balfours and Co.—337
Bedford Electric Light Company—Mtg., 231; Stat., 259
Bell's Asbestos Company—511
Bernstein Electric Lamp Company—Stat., 105
Birmingham Electric Supply Company—Rpt., 510; Mtg., 566; Stat., 739
Blandy's Patents Syndicate—475
Bohm and Co.—Stat., 678
Bourne and Grant Electricity Supply Company—Stat., 309
Bournemouth and District Electric Supply Company Mtg., 650
Brazilian Submarine Telegraph Company—199, 337, 679, 739; Div., 129, 559; Rpt., 738
Brighton and Rottingdean Sea-shore Electric Tramroad Company—105; Mtg., 373
Bristol Tramways and Carriage Company—Rpt., 401
British Electric Light Company—Stat., 739
British Electric Propulsion and Traction Company—739
British South Africa Company—Mtg., 207
British Volta Electric Glow Lamp Company—309; Stat., 739
Brush Electrical Engineering Company—439; Div., 475

21956

COMPANIES' MEETINGS, &c. (*Continued*)—

Cambridge Electric Supply Company—570; Mtg., 565
Central London Railway—439, 621
Central and South American Telegraph Company—Div., 309
Chagford and Devon Electric Light Company—Stat., 511
Charing Cross and Strand Electricity Supply Corporation—Rpt., 439; Mtg., 473
Charing Cross, Euston and Hampstead Railway—621, 739
Chatham, Rochester, and District Electric Lighting Company—51, 309; Mtg., 620
Chelmsford Electric Lighting Company—Stat., 511
Chelsea Electricity Supply Company—Rpt., 437; Mtg., 472, 539, 597
Churchill (Charles) and Co.—Stat., 337
City and South London Railway Company—Rev., 27, 51, 81, 105, 129, 153, 179, 207, 231, 259, 283, 309, 337, 373, 401, 439, 475, 511, 539, 567, 597, 621, 651, 679, 705 739; Rpt., 336; Mtg., 365
City of Bath Electric Lighting and Engineering Company—259; Rpt., 510; Mtg., 537
City of London Electric Lighting Company—361, 511, 539; Rpt., 438; Mtg., 467
Commercial Cable Company—81, 153, 179; Div., 539; Rpt., 567
Consolidated Electric Company—179
Consolidated Telephone Construction and Maintenance Company—511
County of London and Brush Provincial Electric Lighting Company—621, 679
Crompton and Co.—Mtg., 372; Stat., 511
Crystal Palace District Electric Supply Company—337
Cuba Submarine Telegraph Company—Rev., 23, 153, 259, 401, 539, 651; Div., 373; Rpt., 400: Mtg., 437
Direct Spanish Telegraph Company—51, 705; Rev., 51, 153, 259, 401, 539, 651; Div. 511; Rpt. 566; Mtg., 595
Direct United States Cable Company—Div., 283, 651; Rpt., 307; Mtg., 334
District Messenger Company of Paris—337
District Messenger Service and News Company—259
Dover Electricity Supply Company—179; Mtg., 473
Eastbourne Electric Light Company—Mtg., 596
Eastern Telegraph Company—51, 81, 129, 309, 337, 567, 679; Rev., 27, 153, 259, 401, 539, 651; Div., 179; Rpt., 306; Mtg., 333, 367; Stat., 539
Eastern and South African Telegraph Company—81, 679
Eastern Extension, Australasia and China Telegraph Company—283, 597, 651, 679; Mtg., 23, 703; Rev., 27, 153, 259, 401, 539, 651; Div., 179, 651; Rpt., 678
Economic Gold Extraction Company—373
Edinburgh and District Tramways Company—539
Edison Gower-Bell Telephone Company of Europe—Mtg., 621, 651
Edison and Swan United Electric Light Company—567
Electric and General Investment Company—Div., 27
Electric Anti-Corrosion Company—129
Electric Construction Company—Mtg., 80, 129, 179; Stat., 373
Electric Meter Company—373
Electric Welding Company—Stat., 539
Electrical Coal-Cutting Contract Corporation—Stat., 129
Electrical Installation Company—373
"Electrical Plant"—Stat., 373
Electrical Purification Association—373
Electro-Alkali Company—Stat., 178
Electro-Chemical Company—475, 511
Electro-Protector Syndicate—401; Stat., 597
Electrolytic Caustic Soda and Chlorine Trust—Stat., 597
Elmore's Austro-Hungarian Patent Copper Depositing Company—475
Elmore's French Patent Copper Depositing Company—128, 179; Mtg., 152, 204
Elmore's German and Austro-Hungarian Metal Company—539; Mtg., 566
Elmore's Patent Copper Depositing Company—Mtg., 104; Stat., 597
Elmore's Wire Manufacturing Company—539; Stat., 597
Eston Arc Lamp Syndicate—597
Europe and Azores Telegraph Company—Stat., 401
European Sims-Edison Electrical Torpedo Company—Stat., 401
Evered and Co.—Div., 621
Exploration Company—Rpt., 179; Mtg., 207
Ferranti, S. Z. de—Stat., 475
Fibrite Syndicate—597
Financial Movements—373
Ford-Lloyd Manufacturing Company—27
Foreign and Colonial Arc Accumulator Company—597
Fowler-Waring Cables Company—Rpt., 283; Mtg., 308; Stat., 597
Galloways—Stat., 739
Gas Light and Coke Company, 439
General Electric Company—228; Stat., 401
General Electric Company (of America)—27
General Electric Power and Traction Company—Mtg., 176; Stat., 401
General Electrolytic Parent Company—Stat., 439
General Hydraulic Power Company—Mtg., 511
Globe Telegraph and Trust Company—Div., 179, 651
Gold Recovery Patents—567
Gordon Electric Traction Syndicate—597
Gorseinon Electric Lighting Company—Stat., 739
Great Northern Telegraph Company—207, 439, 511, 597; Rev., 51, 153, 283, 401, 539, 651; Rpt., 679; Mtg., 735
Guernsey Electric Railway Company—Mtg., 472
Halifax and Bermudas Cable Company—Stat., 27
Hastings and St. Leonards-on-Sea Electric Light Co. 567; Mtg., 620; Stat., 705

COMPANIES' MEETINGS, &c. (*Continued*).—

Henley's (W. T.) Telegraph Works Company—Rpt., 566; Mtg., 619, 651
Hobart Electric Tramway Company—231; Rev., 401, 439, 539, 705
Holloway Electricity Supply Company—401
Hope-Jones Electric Organ Company—Stat., 597
Hopkinson (J. E.) and Co.—Stat., 597
Hornsby (R.) and Sons—Mtg., 153
House-to-House Electric Light Supply Company—Mtg., 620
Hove Electric Lighting Company—153; Mtg., 178, 565, 597; Stat., 401; Rpt., 539
Howell, J. C.—Stat., 179
Hulett and Co.—Stat., 178
Incandescent Electric Lamp Company—Stat., 401
Indiarubber, Gutta-Percha, and Telegraph Works Company—373; Rpt., 400; Mtg., 435
Indo-European Telegraph Company—Rpt., 678; Mtg., 734
International Electric Storage—651
International Okonite Company—Mtg., 26, 128
Isle of Man Tramways and Electric Power Company 652
Isle of Man Tramways Company—Mtg., 538
Isle of Wight Electric Lighting Company—Stat., 401
Italian Electrical Light and Power Company—401
Kelvinside Electricity Company—129
Kensington and Knightsbridge Electric Lighting Company—Rpt., 400; Mtg., 434
Keswick Electric Light Company—Rpt., 511
Lamina Accumulator (Elieson's British Patents) Syndicate—Stat., 259
Latimer Clark, Muirhead and Co.—373
Lawrence Scott and Co.—Stat., 597
Leeds and London Electrical Engineering Company—Stat., 439
"Lightning"—Stat., 207
Lineff Electric Traction and Lighting Syndicate—Stat., 179
Lithanode and General Electric Company—439
Liverpool Overhead Railway Company—207, 365; Mtg., 436, 509
London Electric Wire Company—Stat., 597
London and Hampstead Battery Company—Stat., 27.
London, Deptford and Greenwich Tramways—475
London Platino-Brazilian Telegraph Company—511, 739
London Refuse Steam Generator and Electrical Power Corporation—597, 621
Machinery Trust—373
Madras Electric Tramways Company—81
Manganese Bronze and Brass Company—337
Mather and Platt—207
Maxim-Nordenfeldt Guns and Ammunition Company—Mtg., 511
Mazarron Electric Light Company—Stat., 678
Medical Battery Company—Mtg., 51, 259, 651
Mersey Railway Company—Mtg., 511
Merveilleuse Electric Arc Lamp Syndicate—Stat., 81
Metropolitan Electric Supply Company—105; Rpt., 705; Mtg., 736
Mexican Telegraph (Cable) Company—Div., 309
Midland Electric Light and Power Company—Stat., 81
Mildé Telephones and Electric Supply Company—401
Miners' Lamp Electric Lighting Company—Stat., 81
Mix and Genest—Mtg., 705
Monte Video Telephone Company—Mtg., 25; Stat., 179
Morecambe Electric Light and Power Company—Mtg., 153, 538; Stat., 439, 511
Mulholland, Maugham and Co.—Stat., 439
Muntz's Metal Company—Div., 511
National Company for the Distribution of Electricity by Secondary Generators—207
National Telephone Company—Stat., 81, 153; Mtg., 307
Newcastle and District Electric Lighting Company—Rpt., 400; Mtg., 436; Stat., 679
Newcastle-on-Tyne Electric Supply Company—Mtg., 400; Stat., 679
New Panulcillo (Limited)—259
New Shanghai Electric Company—Mtg., 154
North-Eastern Telephone Company—Stat., 439
North Staffordshire Railway Company—439
Notting Hill Electric Lighting Company—Rpt., 473; Mtg., 508
Oriental Telephone and Electric Company—437; Mtg., 469, 539, 564
Orme's Electric Signal Syndicate—179
Otis Elevator Company—Stat., 81
Oxford Electric Company—564
Pacific and European Telegraph Company—199; Stat., 439
Pacific Telegraph Company—Stat., 81
Panulcillo Copper Company—81, 129; Mtg., 179, 739
Peru Telephone Company—475
Petzold and Co.—679
Phosphor Bronze Company—Mtg., 679
Pioneer Electric Carriage Company—Stat., 51
Pontypool Electric Light and Power Company—Stat., 475; Div., 567; Stat., 679
Port Beira Pier, Tramway, and Telegraph Company—283, 309
Queen Anne's Mansions Lighting and Heating Company—Stat., 475
Railway Automatic Electric Light Syndicate—Stat., 475
Rainbow Engineering Company—Stat., 51
Robey and Co.—231, 309, 337, 373
Reading Electric Supply Company—651
Rockhampton Gas and Coke Company—Rpt., 621
Rugby School Electric Lighting Company—Stat., 283
St. James and Pall Mall Electric Light Company—Div., 310; Rpt., 336; Mtg., 371, 621; Stat., 679, 705

COMPANIES' MEETINGS, &c. (*Continued*).—

Salt Lake and Ogden Gas and Electric Light Company—81, 283, 337
San Paulo Gas Company, Mtg., 739
Santiago Exhibition—175
Scarborough Electric Supply Company—Rpt., 474; Mtg., 538; Stat., 679
Scott (Ernest) and Mountain—Stat., 179
Sheffield Electric Light and Power Company—679
Smith and Chamberlain—Stat., 679
Southampton Electric Light and Power Company—Rpt., 650; Mtg., 679
South-Western District and Thames Valley Electricity Supply Company—105
Sperryn, Macdonald and Co.—51
Stewart (A. and J.) and Clydesdale—Div., 511
Stock Exchange Notices—27, 28, 179, 231, 401, 511, 539, 567, 739
Submarine Cables Trust—337, 679; Rpt., 738
Suburban Tramways—567
Sunbeam Lamp Company—Mtg., 400; Stat., 679
Swan United Electric Light Company—Mtg., 179, 204; Stat., 475
Taylor and Tucker Art Metal Company—Stat., 51
Telegraph Construction and Maintenance Company—81, 475; Div., 401; Rpt., 474; Mtg., 507; Stat., 679
Telegraph Improvement Company—Stat., 283
Telephone Company of Egypt—Mtg., 650
United Alkali Company—567
United Asbestos Company—Div., 539
Universal Arc Lamp Syndicate—Stat., 259
Universal Electric Lighting Company—705
Veale and Co.—Stat., 51
Venezuela Telephone and Electrical Appliances—179; Stat., 259, 339
Victoria (British Columbia) Electric Railway and Lighting Company—337
Ward Electrical Car Company—Stat., 705
Waterloo and City Railway Company—337, 401, 597, 622
Wenham Company—81
West African Telegraph Company—475
West Coast of America Telegraph Company—208
West India and Panama Telegraph Company—Rpt. 50; Mtg., 77: Rev., 52, 106, 180, 208, 284, 338, 402, 476, 540, 598, 652, 706; Div., 680
West Indian Development Company—105
Western and Brazilian Telegraph Company—Rpt., 50; Mtg., 78; Rev., 28, 52, 82, 106, 130, 154, 180, 207, 232, 260, 284, 310, 338, 373, 402, 440, 476, 512, 540, 567, 598, 622, 652, 680, 706, 740; Div., 567
Western Union Telegraph Company—Div., 232, 567; Rpt., 283, 679
Westminster Electric Supply Corporation—Div., 401; Rpt., 438; Mtg., 471; Stat., 705
Weybridge Electric Supply Company—105
Willans and Robinson—567
Wolverhampton Electric Light and Power Company—705
Woodfield Syndicate—Stat., 511
Woodhouse and Rawson—202, 226
Woolwich District Electric Light Company—Stat., 705
Wrexham and District Electric Supply Company—Stat., 705
Yorkshire Boiler Insurance and Steam Users' Company—Div., 373
Yorkshire House-to-House Electricity Company—Rpt., 474; Mtg., 538

COMPANIES (NEW ELECTRICAL, &c. REGISTERED—

The following Companies have been Registered under the Limited Liability Acts during the past half-year:—

Acme and Immisch Electric Works, 207
Advance Boiler Company, 51
Allan (William) and Co., 678
Altrincham Electric Supply, 621

COMPANIES (NEW ELECTRICAL, &c.) REGISTERED (*Continued*).—
[illegible] Copper Mines, 231
Leppitt (John) and Co., 259
Lis Cabasses Manganese Mines, 401
London Refuse Steam Generation and Electrical Power Corporation, 597
Marine Steam Turbine Company, 373
Mid-le Telephones and Electric Supply Company, 373
Mills (Joseph) and Co., 597
Mosley and Co., 401
New Quay Gas Company, 129
Oriental Telephone and Electric Light Company, 567
Parker, Thomas, 739
Patent Plate Structure Company, 27
Payta to Puira Railway, 129
Port Beira Pier, Tramway, and Telegraph Company, 23
Rose, Downs and Thompson, 178
Ross, James Edwin, 439
Rowland Barnett and Co., 621
Simpson, John, 739
Smith (W.) and Bros., 739
Smokeless Heat and Light Syndicate, 129
South Devonshire Gas Light and Coke Company, 705
Statter (J. G.) and Co., 231
Steel and Garland, 678
Taylor, James, 705
Taylor's Smokeless Boiler Syndicate, 597
Tramway Motor Company, 739
Universal Electric Lighting Company, 178
Valencia and Alberique Tramways Company, 739
Vulcan Gas Engine Company, 739
"Williams" Valveless Engine Company, 739
Willans and Robinson, 567
Yorkshire Steam Valve Company, 439

Companies (New) of 1893, 249
Companies Wound Up in 1893, 250
Condenser-Water Cooler, An Evaporative, *478*, 481
Condensers, Capacity of: by J. Sahulka, 453
Condensers for Electric Light Plants, 215
Condensing Plant, Allen Self-Contained, 381
Conduits, Electrical, Ventilation of, 406
Convection, Electrical, 314
Continuous-Current Arc as a Standard of Light: by André Blondel, 117, 145, 169. (*See also page 164*)

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 807.—Vol. XXXII. FRIDAY, NOVEMBER 3, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

It is a subtle point which is raised by our correspondent "E. M. C.," namely, as to whether human beings possess an ether-sense. Prof. Poynting considers that the "agnostic in ethereal matters" may very well doubt the reality of the ether on the ground that he has no direct sensory evidence of its existence. Our correspondent thinks that the eye is a special sense organ capable of giving this direct evidence. From one point of view it may be maintained that we have no *direct* sensory evidence of anything; for all sensation arises from the energy state of the object perceived, and not from that object inherently. On the other hand, our other senses than sight indicate to us some centre of disturbance, as it were: sound telling us of the sounding body rather than of the air which bears the waves, scents telling of the vicinity of some perfumed object, and so on. So light, which *ex hypothesi* is waves borne on the ether, tells us rather of the source of light than of the ether which conveys its waves. It is a *petitio principii* to assert that the eye is an ether organ; for, at best, it only tells us of a light medium, which, so far as the eye alone is concerned, may be corpuscular on the lines of the Newtonian conception. It is not the sceptic, but the believer, who sees in the phenomenon of physical sight any evidence of the ether as a light-bearing medium.

Neither can the action of radiant heat on the skin be said to constitute an ether sense, except we first make the premiss that such radiation can only be propagated by the ether. Yet, while it is fallacious to suppose there is any sensory evidence of the ether, *per se*, we are equally in a difficulty when we learn that sight and skin-sensation are directly evidences of ordinary matter. When we see a glow lamp, it is true, we have clear evidence that the glow lamp is where we see it; but when we feel sunshine, or see starlight, we feel a radiation eight minutes old, and we see the image of a star as it existed perhaps hundreds of years ago. Both sun and star may cease to exist, yet still we should feel and see them. It cannot be argued, therefore, that sight gives us *direct* evidence either of the ether or of the presence of luminous or illuminated matter. Its evidence, more than that of any other sense, is indirect. In all such questions we must carefully distinguish between the *actual cause* of the sensation (which may be unknown) and the *logical value* of the sensation as a predicate of that cause. Sight may well be actually caused by ether; but it cannot be argued backwards that because there is sight there must be ether.

When, some weeks since, we penned an editorial note on a mathematical method of developing an absolutely constant current from two similar alternating currents, we had no thought of creating such an outburst of practical inventiveness as seems to have been stimulated by it. One contemporary takes us literally for a moment; but on second thought comes to the conclusion that to produce a current which should vary as the square of the sine of the phase-angle would require an infinite induction, because the direction of the current would always be positive. So it would—if there were no commutator; but the true curve of sine-squares might be obtained by means of a suitably fringed magnetic field and a properly adjusted commutator. There is no difficulty whatever in getting an electromotive force to follow the law of squared sines: the essential, and we believe insurmountable difficulty, in the practical use of the theorem, lies in the superposition of two such electromotive forces, in quadrature, without disastrous reaction of each on the circuit of the other. A writer in our Chicago contemporary, *Electricity*, takes up our editorial note and attempts a solution. He arrives at the amusing, if not novel result that, if we superpose a current of the form ($\tan x$) upon another current of the form ($-\tan x + a$) where a is a constant, we shall have an absolutely steady current of strength a. This profound truth dwindles into a vain platitude when we try to see how the current ($-\tan x + a$) is to be formed.

Meanwhile, a detailed account has been published of M. Pollak's device for obtaining steady currents from harmonic electromotive forces, in another and more practical fashion. He synchronises a commutator with the single alternating current with which he wishes to deal, distorts the curve of pressure so that it is much flatter at the top, then clips this curve into useful and useless portions. The useful parts he utilises by coupling them up with the storage battery; the useless portions he leaves to take care of themselves, by putting them on open circuit. It is true that to distort his alternating current into an effective shape, M. Pollak finds it necessary to filter it through a transformer, the core of which is designed to be very nearly saturated at ordinary loads. This is at best a very wasteful process, and may prove, in practice, a very troublesome one. Nevertheless, for the manipulation of small amounts of power, M. Pollak's system appears to give satisfactory and fairly efficient results. One drawback to M. Pollak's method is that it is impossible to measure the

Digitized by Google

current thus produced. For charging a battery, for example, one of the most obvious uses to which it might be applied, nothing but a shunted voltameter would measure the charging current. We know of a private laboratory in London, supplied with alternating current. It is desired to charge batteries with about 2-H.P. continuous current. M. POLLAK's system would be useless for the reasons just given, and it appears that a gas engine and dynamo will be not only the most convenient, but the cheapest way of solving the problem.

WE hear an unofficial rumour that yet another loud-speaking telephone has been invented. 'Tis a consummation devoutly to be wished. And yet we cannot but have our doubts as to the practical success of this latest endeavour to increase the speaking power of the telephone. For, if rumour may be trusted, the inventor claims to have produced an instrument "which will talk loud enough for a person in any part of a large room to hear and understand what is said;" and further, that "the usual induction coil is discarded and the two instruments are directly connected in circuit with the line and battery." Now, quite apart from the possibility of any invention guaranteeing that we may "understand" what is said, it seems to us that it must be next to impossible to arrange a loud-speaking telephone on a primary circuit. It is, of course, of the utmost importance that the efficiency of the circuit shall be high; which it will be difficult to obtain if the high line-resistance is included in the instrument circuit. The whole *raison d'être* of the induction coil is to increase the speaking power of the apparatus, by excluding the line resistance from the circuit whose resistance is made to vary with the sound waves.

THEORETICALLY, and perhaps in practice also, there is no cause which operates to prevent very loud-speaking instruments being successfully invented. The energy of the sound given out by the receiver does not bear any necessary ratio to the energy of the sound put into the transmitter, and may be many times greater than the latter. For, with the use of microphonic transmitters, the operating energy is derived entirely from the source of electric power, such as the battery, and is merely governed by the sound waves. Theoretically, there is no limit to the variation of current in the circuit which may be effected by the feeblest sound waves; but practically, the arcings and sparkings, the hissings and fizzlings, which go on at the microphonic contacts limit the current which will transmit articulate speech to a very small value indeed. When a means shall have been discovered of making a microphonic contact which will modify very large currents without distortion, the problem of loud-speaking telephones will have been solved. The Gower-Bell and other transmitters with several microphones in parallel offer distinct advantages, but it is found that the principle cannot be carried far. There would be no difficulty in constructing a transmitter with several hundred microphones in parallel.

JUDGING from the kind of ammeters and voltmeters which find a ready sale in this country, many electrical engineers are very easily satisfied. Their excuse for supplying inferior cheap instruments is that, except for central-station purpos[es] no accuracy is needed, as their customers want light, o[r in] rare cases power, and do not want to conduct scientific exp[eri]ments. Another reason is that as they could not calibrate instruments themselves, except by comparison with any re[ally] good apparatus that they might happen to have, and th[eir] customers were still less likely to apply any check. On [the] other hand, with the exception of a genuine Weston voltm[eter] in good order, we know of no electrical measuring instrum[ent] that can compare with those of the first-rate English mak[ers]. Makers of high-class watches are reputed to be exceptio[nally] conscientious men, since defects in their goods cannot [be] recognised except by experts. But the rate-keeping of a w[atch] can be proved by the purchaser in a short time, with[out] any expensive apparatus, while the owner of an ammet[er is] generally at the mercy of the maker or agent who suppli[es it]. One tolerably safe rule has been to avoid instruments w[hich] contain much iron, especially in the moving parts. [The] reduction of the iron has led to delicate workmanship in p[ivots] and jewels. Lord KELVIN once proposed the rapid revolu[tion] of an iron core, and provided a handle on the instrume[nt by] which the residual magnetism might be ground out. H[e has] recently adopted the method of saturating the iron by a s[eparate] coil; and to-day we print a short article from Mr. VIGNOL[ES on] an ingenious method of compensation for hysteresis. [M.] ABAKANOWICZ appears to have hit on the same device, w[hich] consists of the use of a steel magnet magnetised b[y the] working current, and serving to demagnetise the iron whenever the working current is reduced or stopped. [It is] not quite clear how an exact neutralisation can th[us be] effected, but the results appear to be very satisfactory.

THERE is often a pomposity about the manner in wh[ich a] third-rate Vestry sets about the question of electric ligh[ting], as if it should say: I am Sir Oracle, and when I ope my [lips] let no dog bark! Until that Vestry "opes its lips" [and] settles the question, electricity is to be regarded as "i[n its] infancy" and quite a matter of theoretical speculation. [But] when it has spoken, then electricity blossoms out into "[the] light of the future," and becomes "reduced to the dead [level] of hard fact." So is it with Camberwell. The elect[ric] committee is now looked upon as the quasi-divine agent [for] reducing "theories to the dead level of facts," and [is] encouraged by the Chairman of the Vestry with the as[sur]ance that "the absence of any knowledge of the subject u[nder] consideration is no bar to efficient adjudication."

Cable Interruption:

	Date of Interru[ption]
Paramaribo-Cayenne	October 25, 18[93]

Award for Arc Light Carbons at Chicago.—In the de[part]ment of electricity at the Chicago Exhibition one additi[onal] award has been made to Great Britain, namely, to the Ge[neral] Electric Company, for arc light carbons.

Institution of Electrical Engineers.—The winter sessio[n of] the Institution of Electrical Engineers will commence [on] Thursday, November 9th, when Prof. George Forbes, F.[R.S.,] will read a Paper on "The Electrical Transmission of P[ower] from Niagara Falls."

Digitized by Google

Telegraphic Communication with the Azores—The Eastern Telegraph Company (Limited) announce that telegraphic communication has been established between the Company's station at Lisbon and the islands of San Jorge, Pico and Terceira. Messages are accepted by the Company at the rate of 10d. per word.

Electric Car Catastrophe in America.—An electric car on the Oregon City Tramway line, containing thirty passengers, went through an open drawbridge in Madison-street last Wednesday and was plunged into Carpen River. So far as can be at present ascertained, twenty-five of the occupants of the vehicle were drowned. A heavy fog was hanging over the city at the time, and the open drawbridge could not be seen.

Brush Plant at Baltimore Burned.—The plant of the Brush Electric Company, at Baltimore, Md., caught fire during the night of October 13th, and was completely destroyed. The Company had the contract for city lighting, and operated the largest plant in Baltimore, having a capacity of over 1,500 arc and 12,000 incandescent lamps. The city will be in darkness, as there is no other company equipped to supply street lights. The loss to the Brush Electric Light Company is estimated at $200,000.

Trade Glow Lamps.—Lamp bulbs of curious and fantastic form are in use in some parts of the United States. Saloons are said to be lighted with clear glass lamps having the shape and size of a beer bottle, and with a paper label stuck on their outer surfaces. Globes having the shapes of cigars, cakes of soap, pickle bottles, &c., are to be found in the shop windows to which they are especially suited. Doubtless in time we shall see, and see by, luminous legs of mutton, glowing geese, and scintillating sausages suspended outside shop windows.

Railway Rates.—The London Chamber of Commerce is constantly being asked by members for advice in regard to paying their accounts with the Railway Companies on the basis of 5 per cent. increase. They have always been advised to pay "on account" only (and not including the 5 per cent.) pending the issue of the report of the Select Committee on Railway Rates which sat during last session. This report may be expected some time this month, and until its tenour is made known the course above referred to is the best that can be recommended.

Electric Light for Lighthouses.—We understand that the Harbour Department of the Board of Trade has decided not to accept the offer of Mr. John R. Wigham, of Dublin, to set at rest, at his own expense, the controversy regarding the relative merits of electricity and other illuminants in lighthouses. It will be remembered that at the recent meeting of the International Maritime Congress, some account of which appeared in *The Electrician*, September 1st, an offer was made by Mr. Wigham to conduct a series of experiments on lighthouse illuminants at his own expense.

The Harness Case.—The *Pall Mall Gazette* states that Messrs. Lewis and Lewis have, on behalf of the proprietor of that paper, accepted service of a writ issued by Mr. C. B. Harness, the late Managing Director of the Medical Battery Company, for libel. Messrs. Lewis, in reply, have informed the plaintiff's solicitors that "our instructions are to give you every facility to bring this case on for trial as early as possible, and to add that in the event of these proceedings being delayed we shall take such steps on behalf of the defendants as the law permits to compel the plaintiffs to proceed to trial."

Electricity in the French Navy.—A remarkable feature of the "Jauréguiberry," the new ironclad which was launched on October 27th from the yard of the Forges et Chantiers de la Méditerranée at La Seyne, near Toulon, will be the extensive use of electricity as a motive power. It will move the turrets, raise the ammunition, and do much other work which in the majority of modern ironclads is done by steam or by pneumatic or hydraulic power. It will also, of course, light the vessel. The ship will contain 550 incandescent lights, and there will be six powerful Mangin search lights.

Opening of a New Technical College.—Hymers College, the new technical college for Hull, was opened by the Lord Chancellor last Saturday. The building consists of a spacious main hall, capable of holding 800 people, and around it are arranged 16 class-rooms and laboratories. The suite of rooms includes chemical and technical laboratories. The estate, comprising the buildings and 20 acres of ground, is the gift of Robert Hymers, Esq., to the town of Hull. The inaugural proceedings included an exhibition of electrical apparatus, and the ubiquitous demonstrations in electric cookery.

Obituary.—Prof. Franz Grashof, the well-known authority in modern engineering science, died at Karlsruhe on October 26th. He was born at Düsseldorf in 1826, and had just completed his 67th year. As a young man he made a long voyage, extending over nearly two years, in a trading ship, to Indian and Australian waters, devoting himself to scientific pursuit. Subsequently rising into fame as an engineer, Grashof was in 1856 elected Director of the Association of German Engineers, and held the post up to the time of his death. Prof. Grashof was the author of a number of text-books on engineering.

Electric Locks.—A system of electrically-controlled locks has been introduced into a Female House of Detention at Baltimore, which it might be found satisfactory to place in every prison and institution where persons are forcibly detained. The women are locked in their cells at night, and, without some such system as that in use, would run the risk of death in the event of a fire breaking out. But all the locks are controlled by an electric switch in the matron's room; and the movement of this switch to the proper contact will release every door in the building, and ring several alarum bells.

Lightning—A New Danger.—Our readers may be interested to learn that Prof. Lodge has commented on the so-called "new danger" from lightning, to which we referred in an editorial note on October 13th, in the following communication to a contemporary :—

> "The note regarding indirect fire from lightning is interesting. It would be difficult to vouch for the occurrence in any particular instance, but I am already convinced that such resonant sparks occur and do cause fires. There is an instance in the Hotel de Ville, Brussels. Gas leaks act as the usual tinder. One would not expect a fringe to catch fire quickly enough."

A Multiple Filament Lamp.—A multiple filament lamp, which has been used for some time in Germany, contains a number of filaments united in common at the upper part; each half can, therefore, be used with any of the others, thus enabling all but one-half of a filament to be used up or broken before the lamp must be renewed; the extra expense is said to be much less than the equivalent in the new lamps. Furthermore, several filaments can be used at once, thus increasing the candle-power. The blackening of the lamp bulb must, however, limit the length of time during which a lamp of this kind might be used, and would probably render it more economical to get a new lamp rather than to continue to use the old one.

Gilchrist Lectures.—Courses of Gilchrist science lectures are at the present time being given in various parts of the country. On Thursday, October 27th, Dr. J. A. Fleming gave the third lecture of the course being delivered at the great Assembly Hall, Mile End-road, E., on "Magnets and Electric Currents." The immense building, which holds 5,000 persons, was completely filled with an audience consisting almost entirely of artisans, who followed with great interest numerous experimental illustrations, chiefly shown with the vertical and horizontal optical lantern. The Ven. Archdeacon Farrar presided. The same lecture was given on the following night to a large audience at Bournemouth

Accident in a Brooklyn Power Station.—One of the big fly-wheels used in the power house of the Atlantic Avenue Railroad at Brooklyn flew to pieces in the evening of October 11th, while revolving at great speed. The bursting of the wheel nearly demolished the power house, partly wrecked a house several blocks distant, broke in doors and windows in other houses, and, besides this, injured three persons. The wheel was 18ft. in diameter, carried a 14in. belt, and weighed about 20 tons. The electric machinery in the power house was, of course, instantly stopped, and all the cars on the Atlantic Avenue lines came to a sudden standstill. The blockade lasted a couple of hours, when traffic was resumed through aid furnished by the wires of the City Railroad Company,

Personal.—His Majesty the King of Portugal has bestowed the following honours in connection with the establishment of

telegraphic communication between Lisbon and the Azores:—Sir John Pender, G.C.M.G., M.P., to be Grand Cross of the Military Order of Our Lord Jesus Christ (His Majesty having offered alternatively to create Sir John a Baron of the Portuguese Kingdom); Sir George Elliot, Bart., to be Grand Cross of the Military Order of Our Lady of the Conception of Villa Viçosa; Admiral Sir George Richards, to be Commander of the Military Order of S. Bento de Aviz; M. Jules Despecher, Mr. Thomas Fuller, Mr. John Denison Pender, and Mr. William Shuter, to be Commanders of the Military Order of Our Lady of the Conception of Villa Viçosa; Mr. Francis S. Harwood, to be Commander of the Military Order of Our Lord Jesus Christ; and Mr. E. V. Wyse and Mr. G. D. Stacey, to be Chevaliers of the Military Order of Our Lord Jesus Christ.

The Official Telegraphic Vocabulary.—The International Telegraphic Bureau at Berne is completing the great work, on which it has been engaged for three years, of the compilation of an official vocabulary for use with code telegrams. It was decided at the Telegraph Conference held in Paris in 1890 that this vocabulary should be undertaken at the cost of the States of the Union, and that the International Bureau should undertake the work, upon which English, Spanish, Dutch, Italian, and Swiss *employés* have been engaged. It will include at least 240,000 words, in selecting which the best vocabularies already in use (including the "Telegraph Convention Codes") have been utilised. The words are drawn from eight languages—English, German, French, Italian, Spanish, Latin, Portuguese, and Dutch. It is thought that the work of compilation will be completed in March next, and that towards the end of 1894 the Vocabulary will be on sale. Three years will be allowed for the general adoption of the vocabulary by the European States, and it is probable that the International Telegraph Congress, which will meet at Buda-Pesth in 1896, will make its use obligatory in all the States of the Union. This Vocabulary should not be confused with a code of prearranged sentences. It is simply a very full collection of words to be used in compiling code sentences. All words which, owing either to their orthography or similarity in telegraphic signals, are liable to error in transmission, as well as those exceeding ten letters, have been eliminated. The numeration of the words is in two sections, the thousands appearing at the top of each page, and the hundreds, ten, and units before each word. After each series of ten words are two words without numbers, which have been introduced to permit the replacing in future editions of numbered words which practice may prove to be inadmissible without necessitating the alteration of the consecutive numbering.

Taunton.—Dr. Fleming has forwarded to the Electric Lighting Committee of the Taunton Corporation his report on his improvements and additions to the electric lighting station. The report is divided into four parts. (1) The additions to the boiler plants; (2) the additions to the dynamo plant; (3) various small improvements required in the station, and especially the alteration of the steam piping; (4) the laying of the mains underground. He reports that the two Babcock boilers now in use at the station are, as far as he can learn, in fair condition. Practically the whole boiler power in the station is under use at the time of heaviest load, and there is no other reserve boiler power in case of one of the boilers breaking down; nor is there any possibility of extending the lighting without overloading the boilers. He therefore recommends the Committee to put down an additional boiler equal to 100 H.P., and this boiler should be devoted entirely to the arc lighting station. He recommends the acceptance of the tenders of Davey, Paxman and Co. for a steel economic steam boiler at the cost of £385, together with £50 for setting it. The next point on which Dr. Fleming lays stress is that it is absolutely necessary to put in at once a small alternator to take the load at times when it is very far below the full capacity of the two present alternators. He also recommends that to drive this machine an engine capable of undertaking about 40 H.P. will be required. Under these conditions he expects to produce a marked economy in the coal. He thinks that the present Willans engine requires overhauling, as does also the Ruston and Proctor engine. Lastly, he deals with a very important question of the supply of the current by underground conductors, and says it will be necessary for the Committee at once to commence putting some c the lines underground, but it is necessary to do this on systematic plan. He proposes to get rid of the small hous transformers, or rather to keep them for what may be calle the "pioneer" work, and to supply the central portion of th town from one common set of transformers which are to b placed in sub-stations.

Science in Public Schools.—The new science building whic has been erected by the governors of the Leys Schoo Cambridge, was opened on Saturday, October 28th, by Lo Kelvin. The building, which has cost a little over £4,00 contains four laboratories on the ground floor, chambers in tl basement for electrical work, three lecture rooms upstairs, tl largest of which has been named the Kelvin room, and vario other rooms for scientific work. The style follows out tl permanent plan of the north block of the school, and the obje of the governors in establishing a science department has bee to enable the boys to go into the University thorough prepared to enter upon a scientific course of education, a well grounded in practical work. At the luncheon, which w held in the school hall, and over which Dr. Moulton, the he master, presided, there was a large number of heads colleges, and scientific and other guests present. Dr. Moult said it was through the powerful and attractive influence the University that the Leys School was drawn to Cambridg Lord Kelvin spoke of the advance made in science teachi since he joined the University 52 years ago as a member Peterhouse. Their fondest anticipations at that time as what might be done never came up to that which had be realised. In those days they had nothing but mathemati and classics in Cambridge, and the undergraduates who to advantage of the teaching of great men in any other branch of instruction were exceedingly rare. Progress, however, h been made since then in the teaching of science in the ancie public schools. He hoped that all the glories of the old publ schools would not in any way be diminished, and that t splendid results attained in classics would not be made le but rather enhanced, by the introduction of other branches instruction. He begged, however, that classics should not l made so very hard and exhausting, and should not be allow to take up the whole of the time at school as they had done the past. It was possible to send out boys from their publ schools showing the best results of a classical education, a at the same time having a good deal of knowledge of math matics and experimental science. The public schools we showing strong and praiseworthy determination to meet matte in that respect. Many of them now had physical and chemic laboratories; but he doubted whether any of them had bett arrangements than those which had been established at the Ley School. The school might be held up as an example to all th ancient public schools which had not already got something a good. He should like to make it known that for a thorough going classical scholar science was a recreation. While losin nothing of the thoroughness of his classical work he migh have his mind opened and refreshed by turning to something else that would be his possession as long as he lived. On the other hand, he did not wish to see science students go out int the world without a fair knowledge of classics; but here there was a difficulty, because if the knowledge was to include verse and prose, Greek and Latin, it was beyond the possibilities o human nature. He did think, however, that classics an literary studies and history were quite necessary for every science student. There was now too much specialising. The object of a public school or University was not to allow a young person entirely to choose that which he liked best. If a boy was very fond of mathematics, for instance, a certain amount of compulsion should be put upon him to learn other things as well which he would not otherwise learn. After referring to the great services which the University had rendered to science, he remarked that it was not imagined 20 years ago that a public school would be equipped as the Leys School now was, and that practical training would be given in the natural sciences in order that pupils going up to the University might be properly prepared for University work. Such a change was comparable with the great revival of learning 300 years ago

ELECTROMAGNETIC THEORY.—LVII.

BY OLIVER HEAVISIDE.

(Continued from page 664, Vol. XXXI.)

§ 217. Let us now ask what is the evidence in favour of the beneficial action of self-induction. There was plenty in 1887; it is overwhelming now. But there are two sorts of evidence, the theoretical and the experiential. The two are not fundamentally different, however; only the former is more indirect than the latter. We have certain electrical laws established, mainly by laboratory work followed by mathematical investigation, and there is no reason whatever to suppose that they do not hold good out of doors as well as inside. The important thing is to correctly recognise the prevailing conditions and determine their results. Now, if you can be pretty sure that you have done this, and have confidence in your investigations, then you may consider that you prove a thing, even though there may be no direct evidence. Discoveries are frequently made in this way. "A foundation of experimental fact there must be; but upon this a great structure of theoretical deduction can be based, all rigidly connected together by pure reasoning, and all necessarily as true as the premises, provided no mistake is made. To guard against the possibility of mistake and oversight, especially oversight, all conclusions must sooner or later be brought to the test of experiment; and if disagreeing therewith, the theory itself must be re-examined, and the flaw discovered, or else the theory must be abandoned." (Oliver Lodge.) But to convince other people is quite another matter. They may not be competent to understand the evidence. Or they may be fully competent, but not have sufficient acquaintance with the subject; or not have time to examine it; or not have the energy; or have no interest in it. Then, as Elijah said to the priests of Baal, you must "Call him louder!"

Now, the foundation of fact is the experimental facts of electricity and the laws deduced therefrom, though these laws are sometimes more comprehensive than the facts upon which they are based. But there was, in 1887, a certain amount of direct evidence as well, quite enough to make the theoretical conclusions practically certain, by the confirmation they afforded. Assuming the electrostatic theory to be true in telephony (for which, however, there was never any sufficient warrant) we can calculate its consequences. They indicate that the product RSl^2 of the total resistance and the total permittance limits the distance l through which telephony is possible. How big it may be is questionable, on account of the very complicated nature of the problem when the human is taken in as a part of the mechanism. We cannot say certainly beforehand how much distortion is permissible before the human will fail to recognise certain sounds as speech. But the electrostatic theory shows such very considerable distortion even when RSl^2 is as low as 5,000 or 7,000 ohms × microfarads, that it is scarcely credible that any sort of telephony could be practicable if it were much bigger, as 10,000 for example. Perhaps 5,000 might be taken as the practical limit for rough purposes. But experience showed that good telephony was got up to 10,000 and higher, in this country with circuits including underground cables, as well as in America, where long-distance telephony had already made a good beginning. Manifestly the electrostatic theory was erroneous by direct as well as indirect evidence. Now the inclusion of the influence of self-induction in the theory explained these results (and also the failure of iron wires and the success of copper) and pointed out how to improve upon them, viz., by directing us to lower R and increase L in order to increase the value of RSl^2 possible. So there was sufficient direct evidence then to satisfy anyone competent to judge who considered it fairly without being prejudiced by the law of the squares. Since that time, the amount of this direct evidence has been greatly multiplied, and RSl^2 has got up to 50,000, which may be about ten times as great as the probable value under purely electrostatic conditions. But there is nothing critical about 50,000. It might be 500,000 if the circuit were long enough. We may need to reduce R when we increase l, but not in proportion to the inverse square of l, or anything like it.

Any long circuit may be made approximately distortionless if the magnetic side of the phenomena can be made important, and without the inconvenience of the leakage needed to remove the distortion, which leakage, however, is essential when the magnetic side cannot be made important. The useful guide in considering telephony is the size of the quantity R/Ln, the ratio of the resistance to the reactance, the two terms appearing in $(R^2+L^2n^2)^{\frac{1}{2}}$, the impedance of unit length of circuit, apart from the permittance.

The term "reactance" was lately proposed in France, and seems to me to be a practical word. It may be generalised to signify the value of Ln, positive or negative, of any combination of coils and condensers, L being then the effective inductance. When L and the reactance are positive, the magnetic side prevails and the current lags; and when it is negative, the electric side prevails and the current leads.

At present, however, R and L are as before. Now the ratio R/Ln may be very large. If so, the influence of L is small, and we shall have something like the electrostatic theory, provided the range of n be such as to make the ratio always large. But this state of things is quite unsuitable for long-distance telephony. The most suitable state is when R/Ln is a proper fraction throughout the whole range of n; that is, when R is less than the smallest value of Ln. We shall then have approximately distortionless propagation of the type

$$f(x) = \epsilon^{-Rt/2L} f(x - vt),$$

as may be seen by examining the solution for simply periodic waves, and observing that when R/Ln is small we have nearly the same attenuation in a given distance (and also distortion) at all frequencies (not too low), so that the element of frequency tends to disappear altogether, and reduce the formula to the above type.

Practice shows, however, that this state of things is unnecessarily good for commercial telephony, which admits of a considerable amount of distortion. Then R/Ln is not less than 1 throughout the whole range of n, but is greater at the low frequencies and less at the higher. For example, if the lowest value of n be 625, and $L = 20$ (centim. per centim., usual units), the least value of Ln is 12,500. If also the resistance is 5 ohms per kilometre, then R is 50,000. The value of R/Ln is then 4 at the lowest frequency, and 2, 1, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$ at the five successive octaves, the last being at $n = 20{,}000$. Here we have an excellent state of things from $n = 2{,}500$ up to 20,000, and only at the low frequencies does R prevail over Ln. If R be halved, or L be doubled (for it is indifferent which is done), then R/Ln is less than 1 from $n = 1{,}250$ upwards. Divide n by 2π to obtain the frequency. This 2π has nothing to do with the ridiculous 4π which the B.A. Committee want to consecrate. The significant point in calculations of this kind is the position of n in the scale of frequency which produces equality of R and Ln. When it is low we have good quality; when high, then relatively bad. Perhaps the American electricians may be able from their extended experience to give practical information on this and other points concerned in telephony, and construct an empirical formula of a sound character for determining the limiting distance roughly in terms of the electrical data, with given kinds of instruments for transmission and reception. It should be understood that the above remarks do not apply to short lines, at least in general. We may, indeed, so arrange matters that the above type is still preserved (with R/Ln less than 1) by practical annihilation of reflected waves, but otherwise serious modification may be needed. And with very short lines we may apply a purely magnetic theory, of course.

§ 218. Supposing, now, that practicians have come to discard the supposed limitations so persistently asserted by official electricians in England, and to open their eyes to the part played by self-induction, they will naturally recognise the wide possibilities that are suggested in future developments, and want to know whether such possibilities can be converted into actualities, and whether the conversion is practicable. For myself, I am not much concerned in this part of the question. It is for practicians to find out practical ways of doing things that theory proves to be possible, or not to find them if they should be impracticable. Nevertheless, since I am responsible

Digitized by Google

for these views concerning the parts played by self-induction and leakage, I add a few remarks on the applicational side.

The ideal is the distortionless circuit, requiring both self-induction and leakage. If we utilise the present existent inductance only, then the needed leakage may be too great by far in many cases. On the other hand, if the existent inductance is big enough to make R/Ln small, in the sense described in § 217, we do not want the leakage particularly, or not at all practically, it may be. It is clear, then, that we should aim at making L/R, the magnetic time-constant, as big as possible.

Now, here is one way of doing it. If, a few years ago, an old practitioner was asked to put up a long-distance telephone circuit, he, being under the belief that R should be high, or at least that it need not be small, and that L should be as small as possible, in order to prevent the deleterious action of self-induction, would probably carry out his principles by putting up a circuit, several hundred miles long, consisting of a pair of fine wires, put quite close together. Or, if he was free from the error as regards R, he would use larger wires. But still close together, for that makes L the smallest. Also, he would not consider this to be bad as regards S, the permittance, being under the belief that the permittance of the circuit of two wires was just one half that of either with respect to the earth, so that their proximity did no harm in increasing condenser action, whilst it destroyed the deleterious self-induction. Now, such a circuit might do very well for local telephony, but for the purpose required there could not be a worse arrangement. The supposed case is not an extravagant one, since it involves the carrying out of official views thoroughly. The cure would be quite easy. Increase the inductance by separating the wires as widely as possible or convenient. If necessary, reduce R as well. The permittance will also be reduced in about the same ratio as the inductance is increased. By this simple process L may be largely multiplied, say from 2 to 20 (cm. per cm.), a tenfold magnification, without separating the wires so much as to require a double line of poles. This way of doing it is the secret of the success of the long-distance telephony which arose in America when iron was discarded. L is made important, and R is kept low. But although L increases very fast on initial separation of wires, it does not continue to increase fast on further separation, so that practical limitations are soon set to the process. The above example shows how a very bad line may be turned into a very good one by increasing the inductance.

Another way is suggested, but only to be immediately rejected. It is, nevertheless, instructive to study failures. We can increase L to any extent by using finer and finer wires. This would be admirable if it were all. But, unfortunately, this process alters R, and faster still; so that R/L increases instead of diminishing. Consider, for simplicity, merely a wire with a concentric tube for return. Then R/L is nearly proportional to RS. Now Lord Kelvin gave a formula long ago, showing that this quantity was made a minimum when the radii of the tube and wire bore a certain ratio. Then L/R is a maximum, approximately, and on decreasing the radius of the wire it falls off, ultimately very rapidly, which is the reverse of what is wanted.

A third way must also be immediately rejected. By using iron wires we can increase L largely with steady currents. But then the skin effect, or imperfect penetration, becomes important with telephonic currents in iron wires. It does two things, both harmful. It lowers L and increases R. So we do not get the large increase of L suggested at first, but only a comparatively small one with currents of great frequency, and we do get a lot of extra resistance that should particularly be avoided. Iron wires are failures for long-distance telephony, as was found long ago.

The case of copper-coated iron or steel wires is doubtful. Such wires were used in America, and it was said that they were successful for long-distance telephony. But here, evidently, the copper is very important in giving conductance. As regards the interior iron core, it must be considered very questionable whether it can be so good as an amount of copper of the same resistance (steady). It is not well placed for increasing the inductance, and the imperfect penetration will operate injuriously.

If we put the iron outside the copper the iron will be better situated for increasing L for steady currents (which is no good), but will act injuriously with rapidly oscillating currents, a[nd] partly prevent the utilisation of the conductance of the copp[er] if it be thick enough to make the increased L important.

The above considerations show that if iron be introduced [to] increase the inductance it should not be in the main circu[it] but external to it. There are, then, two principal ways su[g]gested. First, to load the dielectric itself with finely-divid[ed] iron, and plenty of it. This is very attractive from t[he] theoretical point of view, as it results in the production o[f a] strongly magnetic insulator, which is practically homogene[ous] in bulk, being, therefore, a sort of non-conducting iron of l[ow] permeability. In this way L, as compared with the same wi[th]out the iron, may be multiplied greatly. There is a partia[l] counteractive influence, however, due to increased permittan[ce]. This plan is interesting, in view of the wave theory. It is l[ike] multiplying the μ in ether, and lowering the speed of p[ro]pagation, but at the same time allowing waves to keep [up] against the resistance of wires they may be running along. [But] as regards the practicability of this plan I say nothing, exc[ept] that I have often smiled at this ironic insulator (in more t[han] one sense ironic), and the idea of telephoning through a c[able] resembling a poker with a copper wire run through the mid[dle].

The other way is to put the divided iron outside the work[ing] dielectric. Then it had better not be divided into partic[les], but, in the way well known to dynamo and transformer peo[ple], cut up so as to facilitate the flux of induction, whilst be[ing] electrically non-conducting transversely thereto.

Now it may be said that submarine cables of the present ty[pe], having cores surrounded by a large quantity of iron, have la[rge] inductance already. But it does not follow. If the iron wa[s] a solid tube, then undoubtedly L would be much magni[fied] with steady currents. But it is not a solid tube, as it cons[ists] of spirally laid separate stout iron wires. The magnetic c[on]tinuity is interrupted, and the permeance is much reduced. [As] Prof. Hughes pointed out (equivalently) some years ago. [And] besides that, when the current is not steady, we do not uti[lise] the iron even in the above imperfect manner. This is [par]ticularly the case with telephonic currents, when imper[fect] penetration will still further reduce the effective inducta[nce]. So the increased L due to the sheath must be far less than [the] large quantity of iron might suggest. Again, there is [the] increased resistance due to the sheath not being prop[erly] divided to prevent it. The case is therefore a considera[bly] mixed one. Whilst we can say with confidence that with [the] very slow signalling which obtains through an Atlantic ca[ble] the sheath cannot make much difference, it is not easy [to] decide whether its action is beneficial with telephonic current[s] [to] any great extent, though it would be if there were no increa[sed] resistance. It is not even easy to say what is the L of a s[ub]marine cable under the circumstances. A least value is rea[dily] obtained, but the magnitude of the increase due to the iron [and] the outside return current is rather speculative. It may [be] well-deserving of attention to change the type of the i[ron] sheathing, so as to increase L and keep down R. Remem[ber] here, that although there is plenty of evidence of the benefi[cial] (and very important) influence of this principle when it [is] carried out in a direct and natural manner, there is, so far a[s I] am aware, no experimental evidence yet published of the eq[ui]valent success of indirect ways involving the use of iron.

Another indirect way is this. Instead of trying to get la[rge] uniformly spread inductance, try to get a large average ind[uc]tance. Or, combine the two, and have large distribu[ted] inductance together with inductance in isolated lumps. T[his] means the insertion of inductance coils at intervals in [the] main circuit. That is to say, just as the effect of unif[orm] leakage may be imitated by leakage concentrated at disti[nct] points, so we should try to imitate the inertial effect of unif[orm] inductance by concentrating the inductance at distinct poi[nts]. The more points the better, of course. Say m coils in [a] length l, or $2m$ coils of the same total inductance, [and] therefore each of half the inductance; or mn coils each [of] one n^{th} the inductance of the first. The electrical diffic[ulty] here is that inductance coils have resistance as well, and if [it] be too great the remedy is worse than the disease. But it wo[uld] seem to be sufficient if the effect of the extra resistance [be] of minor importance compared with the effect of the increa[sed]

inductance. This means using coils of low resistance and the largest possible time-constants. For suppose 4 ohms per kilom. is the natural resistance, and there be one coil per kilom. having a resistance of 1 ohm. This will raise the average resistance to 5 ohms per kilom.; and if the time-constant be big enough, the extra inductance may far more than nullify the resistance evil. The same reasoning applies to coils at greater intervals, only of course in a more imperfect manner. To get large inductance with small resistance, or, more generally, to make coils having large time-constants, requires the use of plenty of copper to get the conductance, and plenty of iron to get the inductance, employing a properly closed magnetic circuit properly divided to prevent extra resistance and cancellation of the increased inductance. This plan does not belong to the category of those mentioned before, which a moment's consideration showed to be worse than useless. It is a straightforward way of increasing L largely without too much increase of resistance, and may be worth working out and development. But I should add that there is, so far, no direct evidence of the beneficial action of inductance brought in in this way.

The combination with leaks does not need any particular mention in detail after what has been already said relating to the distortionless circuit, which is the theoretical ideal, any approach to which is desirable if it be done without too much loss; bearing in mind, too, that we should increase L first in preference to putting on leaks first. I have confined myself so far entirely to my theory of 1886-87 and results thereof. Inductive shunts involve some other considerations, and a modified theory.

(To be continued.)

PRIMARY BATTERIES IN THEORY AND PRACTICE.*

BY W. R. COOPER, M.A.

PART II.

(Concluded from page 695, Vol. XXXI.)

Electric Lighting.

The production of light by primary batteries has been a favourite subject of many inventors, but, like the discovery of the philosopher's stone, has always eluded success. The fact, however, that it has not been accomplished is no ground for saying that it is impossible. Our present method of obtaining light is no doubt very defective. It is useless to speak of the high efficiency of the dynamo when the very low efficiency of the steam engine enters into the question. A double transformation of energy is involved with very heavy loss in the first; whereas in the primary battery we have direct transformation with very high efficiency. But in the one case we are consuming coal, and in the other zinc, costing about thirty times as much. Under these circumstances the two systems cannot very well compete. Two courses suggest themselves: either the working substances must be cheaper, or the by-products must be utilised.

A battery for electric lighting should fulfil several conditions. The current should be constant, the E.M.F. high and constant, and the internal resistance small. It should be cheap, small, and easily handled, and there should be no waste or deterioration on open circuit. All these conditions are somewhat difficult to comply with in the same cell.

In looking over the past attempts, one cannot fail to be struck with the small cost of production which is given in many cases, as shown in the following table:—

Battery.	*Cost as stated.*
Ross	= gas at 3s. 6d.
Regent	= gas at 6s.
Upward	= gas at 7s.
Weymersch..................	0·75d. per 30-watt lamp-hour.
Renard	0·2d. „ c.p. hour.
O'Keenan	0·5d. „ 12-c.p. lamp-hour.
Holmes and Burke......	0·5d. „ 10-c.p. „ „
Newton	0·16d. „ „ „ „
D'Humy	0·25d. „ „ „ „

As it is hard to obtain information as to the cause of failure, it can only be concluded that the above figures did not generally include all the items of expense. These attempts were chiefly made in the years 1886—1888.

Among those that promised to be particularly successful, mention may be made of the Lalande battery. It consisted of an iron vessel, A, containing KOH solution and zinc plates, with wire gauze, G, containing copper oxide, between these and the iron vessel (*see* Fig. 21). These were used to charge a secondary battery. To supply 10 lamps of 10 c.p. for five hours per day, two sets of six cells were required, and they had to be completely refilled every fortnight. This battery was reported on very favourably, and it was estimated that the Zn could be recovered as sulphide of zinc white paint, giving a net profit of 9s. 1d. on each battery charge.

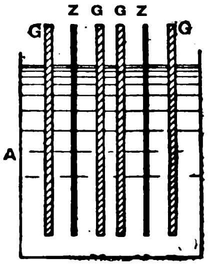

FIG. 21.—Lalande Cell. A, Iron Vessel; Z, Zinc Plates; G, Iron Gauze containing CuO.

A distinct departure was made in the Upward battery, in which gaseous chlorine was one of the active agents. The cells consisted of an outer vessel containing carbon rods packed in crushed granular carbon, and an inner porous pot containing the zinc rod (*see* Fig. 22). A little water was added occasionally, and chlorine was passed into the porous pot. Zinc chloride was formed; and, being very deliquescent, it passed to the carbon, maintaining it moist, the surplus being drained off from the outer vessel. All the arrangements connected with this battery were very ingenious, but it was not a success from a commercial point of view.

FIG. 22.—Upward Cell.

Maquay Primary Battery.

Many will have noticed at the late Electrical Exhibition a stand which was devoted to electric lighting by the Maquay primary battery. Upon applying to the Maquay Electric Light Company they kindly furnished me with the following particulars:—

"The Maquay battery is the outcome of many years' work on the inventor's part, to find a primary battery sufficiently compact to be used for lighting purposes.

"It was the inventor's fond hope that this battery could be used on a large scale, but the cost of the materials for consumption has prohibited its being used for installations, and it is now chiefly used for miners', divers', cycle, bedroom, carriage, and portable hand-lamps, where an excessive candle-power is not required.

"The inventor patented a most ingenious method of automatically feeding the large batteries, so as to keep the solution at a constant density, and also an arrangement to lift the zincs out of the solution and cut off the feed automatically when the last lamp was turned out.

"As now made, the zincs and carbons are attached to a board which can be raised or lowered about an inch, and the board is

Digitized by Google

held in position (when raised) by a clip, which prevents the battery wasting when the light is not required. The zincs are very small, and are arranged to just last out the solution, so that new zincs must be attached every time the battery is recharged. They have a small hole in them that passes over a knob on the zinc holder, and a screw comes down to clamp them; the zinc holder is provided with spring-clips to attach it to the battery, so that the operation of changing the zincs is as simple as it can well be.

"The zincs themselves are part of the patent, and they are painted on one side with a special paint that scales off at a temperature of 65°F., so that when the solution has been reduced to about half its strength, a double surface of zinc is exposed to its action.

"The battery is usually arranged to give 0·5 ampere current for eight hours. It is advisable not to draw more than four amperes from it, and it can be arranged to run for any specified time up to twenty hours. . . . The elements are zinc and carbon in a modification of the ordinary bi-chromate solution. It gives two volts per cell on open circuit and 1·4 volts per cell through the resistance of a lamp, and the polarisation is inappreciable.

"The cost of re-charging this battery is 1d. per cell per eight hours or 1s. 3d. per candle-power hour, or £1. 9s. 2d. per Board of Trade unit."

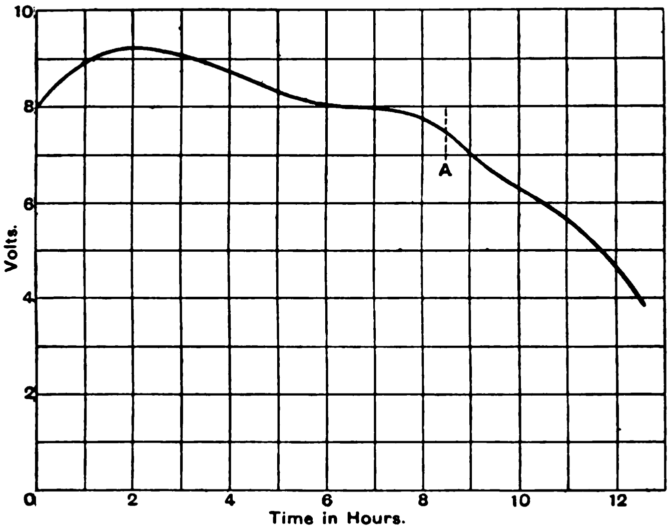

FIG. 23.—Curve of Discharge of a Six-Cell 8½ hour Maquay Battery, lighting an 8-volt Lamp, normally Discharged to the Point A.

The Company have also forwarded me a curve of discharge of a six-cell 8½ hour battery, used for an eight-volt lamp (*see* Fig. 23). There appears to be a variation of about 1½ volts in the 8½ hours, but I am informed that the battery will run without difficulty for another four hours, and that the light in the present case was still bright after 12 hours' discharge.

By-Products.

Although the utilisation of by-products presents an enticing appearance, it is hard to accomplish. It is practically impossible on a small scale, and even at the General Post Office, where there are thousands of cells, Mr. Preece never attempts it. It seems only commercially possible on a large scale by combining a central station with a chemical works. Success would appear to be more easily attained by considering electricity as a by-product. If some of the chemical operations in manufacture could be so conducted that the energy is transferred, instead of being converted locally into heat, then electricity would be obtained simply as a by-product. This may also be done by other means. For example, the utilisation of waste heat presents a problem of considerable interest, and, in connection with this subject, it may not be altogether out of place, in concluding this Paper, to allude to the generation of electricity by heat.

If a circuit consist of two dissimilar metals, and one of the junctions is at a higher temperature than the other, there is a resultant E.M.F. This, in general, increases as the differen of temperature is increased. The E.M.F. per degree is kno as the thermo-electric power of the couple. Thus the thern electric power of bismuth and antimony is about 100 microvo per degree centigrade.

Reference was recently made in *The Electrician* to t Gülcher thermo-electric battery employed at Freiburg in t chemical laboratory. It is employed to charge eight sma accumulators, the heat being obtained from ordinary gas, a it is no doubt very convenient when power is not availabl It consists of sixty-six elements: its mean voltage is 4·1 volt and internal resistance 0·68 ohm.

The utilisation of waste energy is attempted by the Gira thermo-electric stove, being introduced by Messrs. Rensha and Co. It consists of a slow combustion stove for domest heating, and is surrounded by 850 elements, composed copper and a brittle alloy, consisting chiefly of antimony a zinc with Cd, Cu, Sn, and Si. These elements are formed in rings, and are placed round the iron tube of the stove, bei separated from it by asbestos and sodium silicate. Since he is required from the stove, the conditions are somewhat anta nistic to a good effect. The hot junctions are at a temperatu of 380deg. to 420deg. centigrade, and the outer junctions about 120deg. The E.M.F. is about 40 volts; the inter resistance diminishes with rise of temperature, but stands the somewhat high figure of 11 ohms. It may be used charge eight accumulator cells, and will light five or six lan of 8 c.p. by that means for five hours. The inventor hopes be able to apply the principle to the utilisation of waste h which must so frequently occur.

In conclusion, my thanks are due to several gentlemen a electrical firms for the ready manner in which they h supplied me with information, and especially to Mr. Aylr and the Maquay Electric Light Company, who have kin sent round a variety of cells to supplement the informat which I have attempted to bring before you.

THE EDUCATION OF ENGINEERS.*

We believe that the present system, or want of system, of tr ing engineers is very defective. We find, on the one hand, utmost reluctance manifested by civil engineers in practice to pupils, articled or otherwise, at any price. There is incred difficulty encountered in placing a youth in any shop to le mechanical engineering. It can only be done by the aid of "l *and* money;" that is to say, interest in some shape or othe necessary. There are two reasons for this. One is that n heads of firms dislike to take apprentices, and that those fi which will take them have ten times as many applications as th are vacancies. The result is that young men bent on being e neers are driven to the colleges, which are entirely incapabl turning out either mechanical or civil engineers, although they when well managed, perfectly competent to give a prelimin training, which may be useful in after life. But the techn college might be made much more useful than it is were it wo while, which we doubt. Let us compare the training gi to a young man who wishes to enter the medical pro sion, with that given in a college to a would-be engineer. former must spend five years in learning his profession bef he can obtain his diploma. There are various ways in which training is effected; but they differ more in matters of detail t in principle. Before a youth can get into one of the great Lon hospitals as a student, he must have passed an examinatio general knowledge, such, for example, as the matricula examination at London University. From the moment he en the hospital until he leaves it, his course of training is of most practical character. Theory finds no place in it until comes to study physiology. The whole duty of everyone in hospital is to keep patients alive as long as possible, to cure th and to alleviate suffering. Every day, and all day long, student is taught how this is to be done. Who does the teachi Who deliver the lectures? Who perform the operations? fessors, men who have nothing else to do but teach, and who paid for teaching? Absolutely nothing of the sort. There are professors of anatomy, or medicine, or anything else of the k on the regular staff of London hospitals. The whole of teaching is done by men practising their profession, and it is al

* Abstract from *The Engineer*.

Digitized by Google

entirely done without fee or pecuniary remuneration of any kind. These men are all practical surgeons, practical physicians, of the highest eminence. It will be seen at a glance how infinitely superior must be their teaching and their example to that of any professor, however able or clever. Let us suppose that it was possible for 20 or 30 young men to be taken as pupils by some great firm of mechanical engineers, and that the heads of this firm delivered from time to time lectures on every conceivable aspect of engineering. Let the shop training be elaborate, careful, and continuous. At the end of the first twelve months let the pupil go up and pass a preliminary examination, the questions being prepared, as the result of long experience, in such a way that they will most fully test the elementary information which has been acquired during a year by the pupil; and if he fails to satisfy an independent Board of Examiners, all practical engineers, let him be sent back to the shops for three, six, or even twelve months. Let him, if he passes, go on for another year, and then pass an examination in some one special department of engineering. Then, at the end of another year, pass a third examination, in some other special department. Then, at the end of five years, pass two distinct examinations before two separate bodies before he is allowed to practise his profession. Such a training would be strictly analogous to that which the medical student undergoes, and it is, we know, believed by very many people that the college training of a young engineer is almost precisely the same. This is simply a delusion, and the difference is this: The hospital is the strict analogue of the workshops. The wards and the operating theatre are the shops in which the surgeons, the physicians, the nurses, and the pupils work. No science college possesses any facilities of the kind, and it is worth notice that Durham and other universities which confer medical degrees, are obliged to send their students up to the London hospitals in order to give them the practical training which cannot be had in a college.

Such a training cannot be had by the young engineer. It is unattainable. It may be added that it is largely held that it is unnecessary. There is much more force in the arguments urged on this side than the technical educator will admit. The great defect of all science education in the present day is that a great deal too much is attempted. A dozen different men are authorities on a dozen different subjects and on nothing else. Each insists that his own speciality shall be taught. There is no discrimination, no regard for the fact that life is short. It is the age for the dissemination of useless knowledge. Are we justified in hoping that in the teaching of engineers, at all events, it may not be forgotten that one man trained in the field or the shop is worth two trained within the walls of a college?

CITY AND GUILDS OF LONDON INSTITUTE.

The annual report of the Examinations Department of the City and Guilds of London Institute, signed by Mr. G. Matthey, Chairman of the Committee, and Sir Philip Magnus, Superintendent of Examinations, which has just been issued, shows a considerable development in the work undertaken by the Institute. The increased facilities now afforded for instruction in technology, as distinguished from pure science, cannot be better shown than by the fact that the number of students in the classes affiliated to the Institute has increased from 2,500 in 1881 to 22,621 in 1893, whilst the number of candidates for the examinations has increased from [illegible] to 10,254 during the same period. The report is of especial interest at the present time, as indicating the new methods adopted by the Institute for the further encouragement of technical education. From 1889 till the present year the City Guilds have made payments to local classes on the results of their examinations after the manner of the Science and Art Department, and for many years these payments formed the only external help which these classes received. But after the passing of the Local Taxation Act which placed ample funds at the disposal of county councils, the Institute withdrew its grants from classes outside the metropolitan area, whilst continuing to register the classes and to examine the students. It appears from the report that, notwithstanding the withdrawal of grants on results, there is no diminution, as might have been expected, but an actual increase in the number of candidates. The improvements introduced this year into the mode of conducting the examinations include a closer adaptation of the syllabuses to the requirements of different localities, the division of subjects into sections following more nearly the principal branches of each trade, and the addition of further practical tests. The Institute has further arranged to forward special reports to local centres on the work done in separate classes examined by the Institute. The report gives full details of the number of classes and of students in attendance at the different centres of instruction throughout the country, and contains a complete list of the London institutions in which technical classes are now held, including those at the Regent-street Polytechnic, the Goldsmiths' Institute, the People's Palace, and the Borough-road Polytechnic. The Institute's registered classes are now found in all the principal towns of Great Britain and Ireland, a list of which is given in Table V. of the report, and examinations were this year held in India, New South Wales, and New Zealand, the number of centres of instruction and examination having increased from 265 in 1892 to 388 in 1893. The work of the department is carried on by 77 acting and 41 consultative examiners, all of whom are experts in their several trades. The examinations embrace all the principal industries of the country, and range from electric lighting and alkali manufacture to plumbers' work and dressmaking.

The Institute is doing important work in endeavouring to raise the standard of teaching in the various trade subjects in which examinations are held. In order that a class may be registered by the Institute, it must be managed by a responsible committee, which is required to submit to the Institute for its approval the qualifications of the teachers employed; and the report states that in many instances "the refusal of the Institute to recognise a teacher has led to the appointment of a more competent instructor." The extracts published from the reports of the examiners show that there has been a general improvement this year in the work sent up for examination. The percentage of failures in some subjects is still very large, but there is a satisfactory increase in the proportion of candidates who have passed the higher grades of the examination.

The practical tests which the candidates are required to pass are carefully arranged with the view to the special branch of the trade in which they are severally engaged, and, owing to the numerous sections into which trades are now divided, the organisation of these practical tests is attended with considerable difficulty. Thus, in boot and shoe manufacture, a candidate may select any one of ten branches of the trade, in each of which separate tests are given, and in mechanical engineering a candidate may elect to be examined in the honours grade as a fitter, a turner, a patternmaker, or a draughtsman. The practical tests are always held in connection with the written examination, and in many subjects form a necessary part of the qualification for a certificate. In addition to its other work, the Institute awards certificates to teachers of public elementary schools who have regularly attended a course of instruction in manual training and have passed the required examinations. The number of teachers who came up for examination this year was 1,141, as compared with 615 in 1892. The percentage of failures has fallen from 42·6 to 33·5. The Institute continues to restrict its examinations in manual training to certificated teachers, and regards the education which such teachers receive in their ordinary normal course as a part of the necessary preparation for giving instruction in this subject. Next year examinations will be held under similar conditions in metal work, with the view of certifying teachers as competent to give instruction in this branch of manual training to pupils of higher grade schools. The report, of which we have given a short summary, affords abundant evidence that the City Guilds, through this department of their operations, are doing a very useful educational work, in the benefits of which every technical school, not only in London, but throughout the country, is enabled to participate. In the appendix to the report are given the names and places of education of the candidates who have taken the prizes offered by the Institute. These consist of money prizes to the amount of £352 given by 16 of the Livery Companies and of 85 silver and 133 bronze medals. A scheme for the inspection of technical classes by educational and trade experts has recently been issued by the Institute, some particulars of which are given in pages of the report.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

MONDAY, November 6th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

THURSDAY, November 9th.

INSTITUTION OF ELECTRICAL ENGINEERS

8 p.m. "The Electrical Transmission of Power from Niagara," by Prof. George Forbes, F.R.S.

FRIDAY, November 10th.

PHYSICAL SOCIETY.

5 p.m. (1) "On the Separation of Three Liquids by Fractional Distillation," by Prof. S. Young, F.R.S., Prof. Barrett, and Mr. Thomas. (2) "On the Critical Constants of various Ethers," by Prof. S. Young, F.R.S. (3) "An Instrument for Drawing Conic Sections," by J. Gillet, B.A.

THE JUNIOR ENGINEERING SOCIETY.

8 p.m. Mr. John Wolfe Barry, M.Inst.C.E., will deliver the Presidential Address at the Westminster Palace Hotel.

SPECIAL NOTICE.

With the next issue of "THE ELECTRICIAN" (10th November) will be published (Gratis to Subscribers) a fine STEEL-PLATE PORTRAIT of Mr. JOSEPH WILSON SWAN.

Last week's number of "THE ELECTRICIAN" completed Vol. XXXI. With this week's issue is published (Gratis) the Index to that Volume.

NOW READY.

Volume XXXI. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.
Cases for binding Volume XXXI., price 2/0, post free, 2/3.

THE PUBLICATION OF PHYSICAL RESEARCH.

The correspondence which was started in *Nature* on the "Publication of Physical Papers," by Mr. J. SWINBURNE, has attracted a good deal of attention, and may be said to have culminated in the discussion which followed the Paper of Mr. BASSET at the British Association. By far the most important feature of this discussion was the official announcement by Lord RAYLEIGH that the Royal Society had appointed a committee to consider the matter. Under these circumstances further discussion of the whole question is unnecessary until some decision has been arrived at by this committee, but there are several minor points, to some of which Mr. E. E. FOURNIER alludes in his letter to us this week, which are worthy of further consideration. Although a general opinion seems to have been expressed that a simple translation of *Wiedemann's Beiblätter* would not meet the case, Mr. FOURNIER discusses this proposal, but admits that the cost might not fall short of the starting of an English periodical. The only existing publications of the kind are the *Philosophical Magazine* and the *Proceedings* of the Physical Society; and some difference has naturally arisen as to the possible modification of these publications, in order to meet the loudly-expressed want. In suggesting a new periodical it must be remembered that the want is more keenly felt in those branches of physics which have little or no commercial side. This means that few advertisements could be expected other than of scientific instruments, new scientific books, and cocoa. And without copious advertisement pages, or else a heavy subsidy, it would be impossible to make such a periodical pay for the mere cost of production. It was pointed out by Mr. SWINBURNE at the

Digitized by Google

British Association that scientific literature is mainly supported by amateurs. It is doubtful if a sufficiently large circulation among these amateurs could be found for a journal of the kind advocated. Extensive circulation is essential if the paper is to attract advertisements. There seems to be a reluctance on the part of English journals, whether daily, weekly or monthly, to admit that, with but few abnormal exceptions, they are dependent upon advertisements for their existence. When M. ZOLA recently called attention to this fact, it was shyly alluded to in the press, but as a matter on which no comment should be made. A glance at the railway bookstalls shows the vast mass of rubbish which appears to have been brought into existence by the compulsory instruction of the masses in reading and other accomplishments. Having learned to read, they must have something to read, but being uneducated, and having no time to be thoughtful, they are content to take whatever trash is offered. And yet a weekly or monthly journal of physics must await the support of the Royal Society!

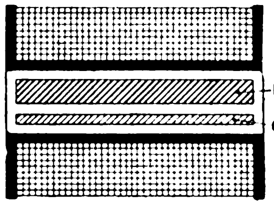
Electrical science is the only branch of physics which has a distinct commercial side, and consequently we are enabled to notice some of the leading work in pure electrical physics. We endeavour to keep our readers informed of most of the important researches in this science, but we are well aware that our record is by no means complete. Some idea of what a thorough record would be, may be gleaned from the careful digest of electrical journals in the *Electrical World* of New York. From this should be eliminated, for the purpose under consideration, all the engineering and industrial applications; but of electrical science alone a large quantity would remain. Lord RAYLEIGH has alluded to the difficulty of censorship. This function, the thankless task of every editor, is discharged with but little difficulty by scientific societies who refer their Papers to members of Council. The anonymity of their decisions is of course convenient, but the duty is not always pleasant. If the commercial element were really eliminated, censorship would be confined to the exclusion of communications to which the authors attached an undue importance, which contained some palpable errors, or which turned out to be old. It is really to avoid this last contingency that the want of some means of publication is so keenly felt, but will not the news often come too late? Would such a journal have prevented the independent construction of magnetic curve-tracers by Prof. EWING and by Mr. SEARLE, working within a few yards of each other at Cambridge, each ignorant of the other's aim; aims which by-the-bye differed considerably, and do not happen to clash.

We do not, as we have already stated, attempt to make in the columns of *The Electrician* a complete *resumé* of electrical physics. The great activity in this branch, due not so much to utilitarian applications as to the purely scientific work of HERTZ and many others, would result in a considerable preponderance of electrical matter in any such record. The scientific news agency which Mr. FOURNIER finally suggests has been tried, but we do not know with what encouragement or success; the samples we have seen were extremely feeble. Such methods of disseminating information appear to be best suited for the supply of press-cuttings on special subjects to subscribers; but for the present purpose each subscriber would probably want news of all the branches, and the cost would be considerably greater than that of a special journal. We are inclined to think that the Physical Society might do for its physics what the Chemical Society has done for chemistry, but still leaving communications on researches of the highest character to the Royal Society, whose action in this matter will be awaited with interest.

COMPENSATION FOR HYSTERESIS.

BY E. B. VIGNOLES.

One of the most serious drawbacks to the use of a magnetic measuring instrument containing iron, in the hands of an unskilled or careless observer, is the liability to errors due to hysteresis; and the attention of inventors has long been directed to the problem of avoiding them. Broadly speaking, the kind of error that takes place in an instrument in which the iron circuit is of nearly the same length as the coil, is about 1 per cent. on reversal at the upper part of the scale, increasing gradually to 5 or even 10 per cent. at $\frac{1}{10}$th of the maximum reading. If an attempt is made to increase the forces working an instrument by making the magnetic circuit more complete, the effort is frustrated by the enormous increase in the hysteresis error. This effect may be produced in two ways: the first is due to the coercive force of the magnetic circuit, and this is the generally observed source of error; but wherever a movement of the working part is accompanied by a movement of a bundle of induction in an iron block or sheet there is an additional local effect due to the reluctance of the iron to accept this change of position of the induction. Were it not for this, a powerful ohmmeter might be made by arranging the pressure and current coils on magnets at right angles to one another, and whose pole-pieces embraced a soft iron needle having a wide end. When the two magnets are equally strong the needle should take a mean position, but such an arrangement has such terrible "local" hysteresis, that it is completely useless. To keep this in mind when designing new instruments may spare the inventor many a useless experiment. The reasoning applies chiefly to powerfully magnetised iron, but is true also to a certain extent of every instrument where the position of the maximum induction in the iron varies.



It is not by any means necessary to eliminate this error, even if the instrument is for use as a standard, but the precautions which have to be taken to ensure accuracy are briefly as follows: the instrument must always be used with the current flowing through it in the same direction, or if this is impossible the full current must be sent through it in the direction in which it is required to be used before any readings are taken; secondly, the current must always be broken just before any reading is taken, in order to ensure that the magnetisation curve of the iron is always starting from the same point, and if these conditions are strictly fulfilled the reading of an iron instrument is absolutely reliable, and it may be used as a standard with very great convenience; the author has had such an instrument under observation for some years, and has never been able to detect the smallest variation at one sixth of the maximum reading.

In order to ensure the least possible hysteresis error the length of the iron in the direction of the induction must be made as small as possible, so as to diminish the coercive force, or, in the old-fashioned parlance, to increase the demagnetising effect of the ends, as has been done in the latest Hartmann and Braun design, which is not otherwise noteworthy.

But it is, perhaps, not generally known that by an ingenious device due to Mr. Evershed originally, I believe, and for which a provisional specification was filed some years ago, the effects of hysteresis can be almost entirely eliminated, and can easily be rendered so small as to be practically negligible. A similar principle appears to have been recently invented by M. Abdank Abakanowicz, whose methods are described in *La Lumière Electrique* and other papers. The simplest form of the Evershed method is illustrated by the adjoined sketch, which represents a section of a coil magnetising the iron cores I and C. Suppose the current tends to make the left side north, and suppose that C is made of hard steel, and has, therefore, a much greater

Digitized by Google

coercive force than the soft iron I. When the current is cut off the core C remains more intensely magnetised than I, and the return path for its induction is partly through I, which is thus demagnetised, and may be reversed. By suitably proportioning the parts the effect outside the core may be entirely obliterated.

Modifications of the method easily suggest themselves. The core C may be outside the coil, and separately magnetised, although this is generally more cumbersome; but it is needless to go into details, as the principle is so very simple; but one of M. Abakanowicz's examples is worth alluding to. He makes a wattmeter whose field is produced by two electromagnets, the main core producing a large field in one direction, and a small and very coercive core producing a small reverse field. The "residual magnetism" of the two may be easily made equal, while when the current is on, the main field is largely in excess of that of the compensator.

The condition for perfect compensation is that the two curves of magnetisation shall be similar, but on different scales; but the author has found that this condition is exceedingly difficult to obtain. It is possible that for standard instruments the method may be of value, but the author believes that Mr. Evershed has not kept up his patent. It is probable that compensation would never be so perfect as to obviate entirely the necessity for the precautions above described. It seems desirable, however, that, in view of the publication of M. Abdank Abakanowicz, the results of our earlier work should be put on record in these pages.

THE POLLAK SYSTEM OF CHARGING SECONDARY BATTERIES FROM ALTERNATORS.*

The essential feature of M. Pollak's apparatus for transforming alternating currents into uni-directional currents is a commutator placed on an extension of the spindle of a synchronising motor, which is driven by an alternate current of the same phase as the one which is to be redressed. The commutator is composed of as many segments as there are poles on the motor. If, for example, this latter has eight poles, there will be eight strips on the commutator, as is shown in Fig. 1. These strips do not, however, fill the periphery of

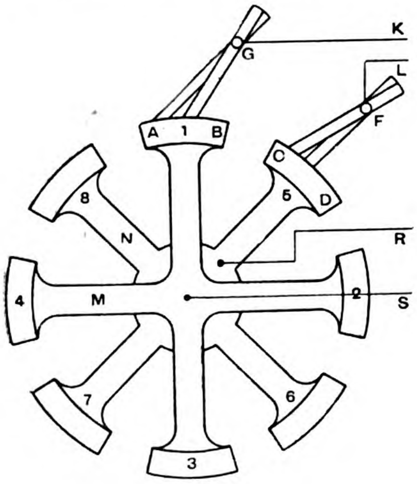


Fig. 1.

the commutator, for there is a considerable gap between the adjacent strips. The segments 1, 2, 3 and 4 are coupled together in parallel on a ring M, which is keyed to the spindle, and are connected to one wire, S, of the alternate-current circuit. The other wire, R, of that circuit is connected to the ring N, keyed similarly to the spindle, and the segments of which, 5, 6, 7, and 8, alternate with those on the ring M. Two brushes, F and G, which make contact with two adjacent strips, as at 1 and 5, are coupled to the wires K and L, which lead to the circuit in which the current is to be used. The result of this arrangement is that four of the segments are connected to the positive terminal of the circuit, and the remaining four segments to the negative terminal; while this polarity is reversed in every eighth part of a revolution. If, at any one instant, the strips 1, 2, 3, 4 are positive, then, when the motor and the commutator have turned one-eighth of a revolution, the strips 5, 6, 7, 8 will be positive; but at this instant the brush G, which in the first instance pressed against the strip 1, will now press against the strip 5. The polarity of the brush G will therefore never change, and the same may be said for the brush F. In consequence of this, the brushes F and G will collect currents always in the same sense.

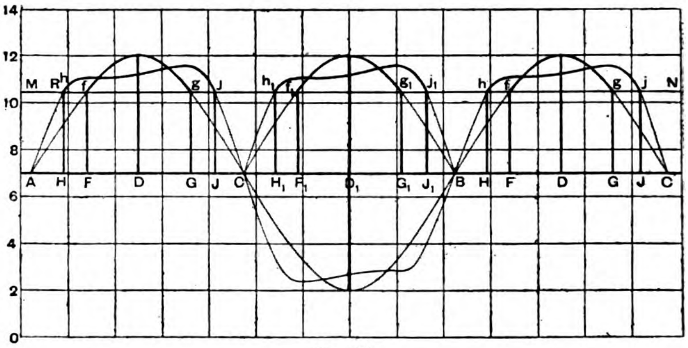

Fig. 2.

If the alternating electromotive force in R, S, is assumed to be sinusoidal, or a simple harmonic, the pressure collected at the brushes will have the general form of a succession of rectified sine curves; A, f, g, C, in Fig. 2 becoming succeeded by C, f_1, g_1, B, and so on. But when it is required to charge accumulators, it is impossible to utilise this redressed electromotive force during its entire extent, because the charging pressure E should always be greater than the counter-electromotive force of the cells E′. If we represent this latter by the straight line M, N, the portions f, g, and f_1, g_1, are alone utilisable. It is therefore essential that the current taken off by the brushes shall not commence before F, F_1, and that it

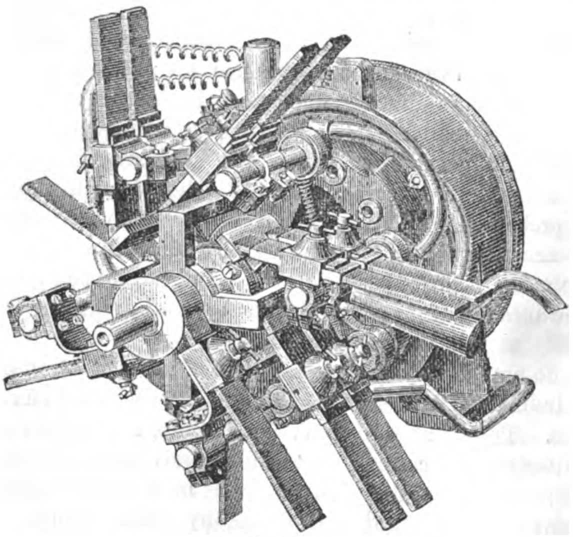

Fig. 3

shall not be continued beyond G, G_1. At these points the opposing electromotive forces in the circuit are equal, so that contact at the brushes is made and broken without sparking. Further, if the contact of the brushes is maintained during a shorter period than F G or F_1 G_1, the energy passed will be less than the area F f g G or F_1 f_1 g_1 G_1, and as a consequence the rate of charging will be less rapid. The duration of the rupture of the charging circuit, G C F_1 or G_1 B F, can be regulated by shifting the two brushes relatively to one another. If we suppose the brushes to consist of mere strips, a and c, it will be easy to see that if they are one-eighth of a turn apart, the length of the segments, such as 1 or 5, will

* From *La Lumière Électrique.*

Digitized by Google

represent the duration of the closure of the circuit F G_1, while the period of rupture will be determined by the distance which separates two adjacent strips on the commutator. The period of rupture can easily be regulated, however, to suit any value of the counter-electromotive force, by shifting one of the brushes forward or backward.

If the electromotive force is represented by a sine curve, the two portions of the period of rupture, G C and C F_1, will be equal. But it will often happen that the curve of voltage is not symmetrical, such as in A $h j$ C, or C $h_1 j_1$ B, where the ordinates are not equal. But it is still possible to effect an exact adjustment, by means of two strips on each brush. Each brush is, in fact, constructed of two brushes, *a* and *b*, and *c* and *d* (Fig. 1), each pair mounted on the same metal holder and therefore in electrical connection, but capable of relative adjustment of their positions. The similar brushes, as *b* and *d*, are manipulated by the same brush rocker and lever.

What is true of one pair of segments, 1 and 5, is applicable to every other pair of contacts which can be made on the commutator. The current, therefore, may be collected all round the commutator by means of four pairs of brushes, arranged so as to develop an effective electromotive force, E_{eff}, equal to E′. For example, for a battery of 35 cells, giving an opposing pressure of 70 volts, it will be necessary to have an effective pressure E_{eff} equal to 70 volts, which will correspond to a maximum pressure of 100 volts. Adopting this rule, and still supposing a simple harmonic current, we find that in Fig. 2 the period of closed circuit, F G, will be equal to the period of rupture of the circuit; these two periods being severally equal to one-fourth of the harmonic period of the current. The energy expended on the battery in one half-period will be represented by the area F $f g$ G which approximately equals three-quarters of the total area, A $f g$ C. Hence the commutator may be said to have 75 per cent. efficiency.

The energy which is not taken up by the commutator, *i.e.*, the part of the curve A f F and G g C, is simply available energy which, however, is not wasted, because during this portion the circuit is open. Theoretically, then, the commutation is no source of loss, but practically we must deduct from the energy supplied that amount of energy which is required to work the synchronising motor and commutator. This actual loss amounts to only 100 watts in a commutating apparatus capable of transforming eight kilowatts, which represents a loss of less than 2 per cent.

With a true sine function the maximum electromotive force will very much exceed the steady counter-electromotive force of the battery, and it would be found that the accumulators would be subjected to a current of greatly varying strength. M. Pollak has got over this difficulty by replacing the sine form of electromotive force curve by a curve shown by A $h j$ C, which he obtains by passing the alternating current through a transformer in which the magnetic induction is such that the iron is brought very nearly up to saturation. The line of counter-electromotive force, M N, will cut this curve in the points h, j, h_1, j_1, nearer to the points of reversal than where the curve is sinusoidal. In consequence of this the duration of the closed circuit condition, H J, will be longer, and the duration of the open circuit condition will be less than in the previous case. It will be seen in Fig. 2 that the area H $h j$ J, which represents the stored energy is very perceptibly greater than the former area F $f g$ G, corresponding to a similar quantity. That is to say, the charging is carried on more rapidly, and at the same time with greater regularity. In fact, the pressure, instead of varying from 70 to 100 volts, is kept at about 85 volts during the whole period of closed circuit, which is much less injurious to the plates in the storage cells.

After the foregoing theoretical considerations it will be easy to understand the practical working of the Pollak commutator, which is shown in Fig. 3. The commutator itself is mounted on an extension of the spindle of a little synchronising motor, having 8 poles, and running directly on the circuit of an alternator. This motor is drum-shaped, 30cm. long and 20cm. in diameter, carrying on an extension of its spindle two vertical brass discs, each composed of four arms surmounted by contact plates or teeth, slightly rounded. The two discs are insulated, and their teeth are interpenetrated or sandwiched so as to form a circular ring of eight segments. The eight brushes for collecting the rectified current are each composed of two strips of copper, mounted side by side on the same brush holder. The eight inside strips, which are insulated from one another, are connected together by springs which are mounted on a ring, which is provided with a handle for regulating the distance between the interior and exterior strips of the same brush. The brush-holders are alternately connected in parallel, forming two series of brush-holders, which are connected severally to the two terminals of the charging circuit. The four brush-holders forming one series are attached to the frame of the machine; the other four are mounted on a movable ring, which can be shifted round by means of a handle.

A Siemens alternator was run at half speed, giving 60 volts, and was connected through a switch to the terminals of a little Ganz motor, on which was mounted the rectifying commutator. When the motor had attained a speed of 300 revolutions per minute, the switch in the circuit of the commutator was closed, and a current passed to the commutator. This current was derived from a small 2 kilowatt Ganz transformer, the primary circuit of which was fed from the Siemens alternator. A voltmeter and an ammeter were placed on the primary circuit of the transformer, the coefficient of transformation of which was equal to unity. The rectified current was employed in charging a battery of 24 cells coupled in series, and having a capacity of 500 ampere hours. A reversing switch, capable of reversing the battery connections, was placed in the circuit together with a pole indicator, this last consisting of two glow lamps. If the contact of the reversing switch left the lamps in darkness, the poles of the commutator were in opposition to those of the battery. On the other hand, on reversing this switch, the lamps glowed, indicating the current in the battery. The position of the brushes to obtain the minimum of sparking would be regulated at this moment. It was easy to render the sparking imperceptible with a current of 30 amperes passing through the commutator. This shows that the Pollak commutator is not merely a laboratory instrument, but a practical apparatus for industrial uses.

In the primary circuit of the transformer the voltmeter indicated 62 volts, and the ammeter 50 amperes. The voltmeter in the charging circuit read 60 volts, and the ammeter of this circuit 40 amperes. The synchronising motor absorbed 100 watts.

THE ARTIFICIAL LIGHTING OF WORKSHOPS.*

BY BENJAMIN A. DOBSON.

(Concluded from page 703, Vol. XXXI.)

Fire Insurance.—With the object of avoiding any difficulty in the future it would seem advisable, before proceeding with the further development of the plan of inverted arc lighting, to consult the insurance companies in each individual instance. The old style of insurance, where heavy risks were taken by one or two companies only, has now been altered, so that in large works such as those here considered, where the amount of insurance may be near £300,000, the risks are divided among a large number of different companies, who in their turn sub-insure their risks in other companies not primarily engaged. There is a tacit understanding between the companies that one surveyor may act for the whole of them in any one particular case, thus judiciously securing uniformity of action. But it unfortunately happened that the four lamps in question, which had been tried for some months at the works of the writer's firm, were lent by them, along with a dynamo and driving power, for the purpose of ascertaining how a certain cotton mill, which had the disadvantage that one corner of the bottom room was darkened by buildings outside, could be lighted so as to replace the missing daylight. The four lamps were placed in position and tested. The result was far beyond expectation. It was found that the cleanliness of the work, which is an essential requirement in cotton spinning, could be supervised to a degree hitherto unattainable by artificial light. The owners of the mill were then anxious to adopt this kind of lamp immediately; but they met with an absolute refusal from the insurance companies to allow any open arc lamp to work in a cotton mill. This led to the question of its further use in the ironworks of the writer's firm, and at first a blank refusal was received, without any reason being given; but correspondence of some months resulted in permission being at

* Abstract of Paper read before the Institution of Mechanical Engineers, on Wednesday, Oct. 25, 1893.

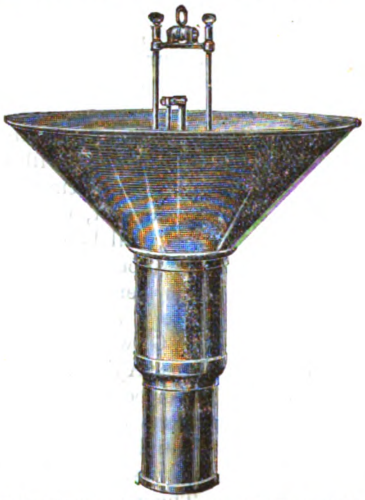
Digitized by Google

length granted to continue its employment under certain rigid conditions. These indeed were reasonable as regards the conducting area of the wires, the voltage, safety fuses, and other necessary precautions.

In order to see whether there could be any valid objection to its use in cotton mills, the author made a fairly complete series of experiments. The danger in cotton mills is supposed to be that the finest fibres or filaments are liable in the process of spinning to escape in a certain proportion, under the action of the draught caused by the moving parts; and being of much the same specific gravity as the air, they are easily carried by upward draught. When they reach any ironwork, either columns, beams, shafting, or gas pipes, they have a tendency, owing to the latent electricity always developed in textile fabrics, to attach themselves radially to the electric or magnetic centre; and as the carding-room air in a cotton mill is always more or less charged with these floating filaments, the insurance companies feared the result of combustion by contact with the open arc would be that the fire would be conducted to a dangerous quarter by the loose filaments adhering to wires, &c. This fear is found to be absolutely groundless. Repeated and extended experiments have in every case failed to show any indication of danger from such a cause. The fallacy of the insurance companies' objection is rendered apparent by the fact that at the present time they allow open gas-jets in all cotton mills. If there were any danger in an open arc lamp, there would surely be more in open gas-jets, which, of course, are more numerous than arc lamps would be. Furthermore, the arc lamps have to be lowered every eight hours of work for the purpose of changing the carbons. The gas jets are turned off when not required, and lighted again when wanted; this may occur two or three times a day. But every time the electric lamp is lowered it is thoroughly well cleaned, which is especially easy, as it consists simply in wiping the wire and the inside of an enamelled reflector. To prove that the arc-lamps cannot convey fire by contact with the cotton fibre, the author has let fall in the inverted reflector quantities of what is termed cotton-fly, being the lightest and most inflammable part of cotton fibre; and as soon as the level of the arc was reached and the top fibres were ignited, the fire spread rapidly round the cone of the reflector, and burnt downwards towards the bottom. When keeping the eye level with the top of the reflector, it was impossible to see anything escape over this level except the black tinder resulting from the combustion of the fibre or fly. With the true cotton itself, smouldering particles might be seen to the extent of from 4in. to 6in. above this level; but it was proved that these smouldering embers had no heat beyond that necessary to give them their colour, for they were not even capable of exploding gunpowder.

For the purpose of further elucidating the question of fire risk, the author visited a mill in Belgium, not far from Ghent, where very coarse numbers were spun, the cotton being of short fibre; and the amount of evaporation, as it is termed, of fly from the lower filaments was particularly great, the cotton used being of the poorest quality. Directly over the carding engines was an arc-lamp of more than 1,200 c.p.; and during four hours spent in watching and noting the effect of the lamp upon the fly, on not one single occasion was the slightest spark visible outside the reflector. Sometimes when the fly was unusually thick in the air, owing to a carding engine being brushed out, a slight corruscation could be perceived near the centre of the reflector, like the twinkling of a star; but this would only occur once now and then. Undoubtedly a certain amount of fly was consumed, because when the lamp was lowered for examination a residue was found in the bottom of the cone, composed of the very lightest tinder of cotton, but utterly uninflammable under any circumstances. In this country the insurance companies declined to countenance any experiment, on the ground that mill owners had been satisfied up to that time with the ordinary gas-light and with their insurance regulations, and therefore they could see no good reason for a revolution of ideas. Furthermore, the definite allegation was made that on two occasions fires had been caused in cotton mills abroad which were lighted with arc-lamps. Feeling the importance of ascertaining what amount of truth there was in this statement, the author wrote to the proprietor, manager, and others interested in each instance. In the first it transpired that not a cotton mill but a cotton store had been burnt, which was lighted not by arc-lamps but by glow-lamps only; and the theory to account for the conflagration was that of spontaneous combustion, which is by no means rare when cotton is stored in bulk. In the second instance, the lighting was not by the open arc-lamp inside an inverted conical reflector, but by an ordinary arc-lamp surrounded with a glass globe. There was an aperture in the bottom of the lamp; and owing to some disarrangement of the clockwork regulating the carbons, a portion of an incandescent carbon had been split off, and falling through the aperture upon a mass of cotton beneath had set it on fire. When cotton in a loose condition does get on fire it is much like a train of gunpowder; and this mill, which was kept in a condition far from clean, being covered with a thickness of fly steeped in oil over the floor, walls, and ceiling, became so suddenly a mass of flame that the workpeople had considerable difficulty in making their exit from the burning building.

Arc-Lamp.—The complete absence of danger from the arc-lamp used by the author will be more thoroughly appreciated from a description of its construction. It consists of two carbons of different diameters, the upper or negative carbon being solid, and the lower or positive carbon being annular and rather larger in diameter. Their areas are 0·200 sq. in. and 0·486 sq. in. respectively: which proportion ensures their both consuming at the same speed, thereby avoiding the necessity of any complicated clockwork arrangement to differentiate the speed of the feed. In this lamp, indeed, there is no clockwork, but the carbons are drawn together by a pulley, string, and counter-weight, their distance apart being regulated in the usual way by a magnetic brake. The pulley, weight, and brake are all contained in a cylindrical box attached to the underside of the cone of the reflector; and the only interruption to the light above is that occasioned by the thin arms forming the clip which holds the upper carbon. The crater carbon is here the lower one, in order that the larger number of rays produced may be thrown upwards. The cone reflector is 25in. wide at the top and 7in. at the bottom, the angle of the cone being 88deg. The interior surface is ordinary white enamel upon the sheet-iron exterior.



Pieper Inverted Arc Lamp of the Compagnie Internationale d'Electricité.

Each lamp is balanced by a counter-weight over pulleys, and the counter-weight hangs conveniently alongside either a wall or a pillar, so that it may not be in the way of traffic. Thus it is easy to lower the lamp for the purpose of renewing spent carbons, which has to be done about every eight hours, and requires not more than one minute per lamp.

Practical Results of Working.—The plan of inverted arc-lighting has now been in use in some portions of the writer's works for 12 and 13 hours a day during the last 12 months, and sometimes almost night and day; and the results of its working he has every reason to believe may be considered successful. The building, as already mentioned, consists of three storeys, each room 123ft. by 55ft.; the bottom room of all is surrounded to such an extent by other buildings that it was necessary to keep the gas burning the whole of the day. In this room the work consists of turning, fluting, polishing, and repairing what are known as fluted bottom-rollers for spinning machines. These rollers require to be finished with mathematical accuracy, and the majority of them have to be channelled or fluted to the closeness of from 16 to 19 flutes per inch, the shape of the flutes being of the greatest importance. In the room above are manufactured top rollers to work on the fluted rollers; these also have to be mathematically correct, and their surface finished to a high degree of accuracy. In the third room are manufactured what are known as flyers, having one hollow leg, through which the cotton must pass down in a slightly twisted condition. Owing to the affinity of cotton fibre for metal affected electrically, however little, it is evident that any roughness of the interior surface of the hollow leg must be prejudicial to the working; and it is, therefore, necessary that the smoothness of finish should be unquestionable. The attic or roof room is used for the storage of patterns, as previously mentioned. In the bottom room there are 51 machines, consisting of lathes and fluting machines and others, and employing 60 workmen. The second room contains 164 machines, employing 139 workmen; and in the third room there are 69 machines and 112 workmen. The only glow lamps used are those in the attic or pattern store, most of which are portable for the purpose of finding patterns on the various shelves; and also, strange though it may seem, two glow-lamps in the bottom room, for the examination and repair of slightly defective flutes. The latter lamps had to be applied because the reflected light from the arc-lamps gives no shadow; and in order to

Digitized by Google

perceive the minute defects in the flute it is necessary to have a light that will give a prolonged shadow, for the purpose of exaggerating what is to be seen. The writer quite thought it would be possible to accomplish the same object by the use of a reflector; but the prejudices of the workpeople were too strong.

When first this mode of lighting the rooms was set going, and the gas turned off at the mains, there was much grumbling of the workmen, who protested it was impossible to perform their work by the new light. This difficulty, however, had been foreseen, and they were informed that as the light had been put in at a large expense for their comfort and health, they must, at least, give it a fair trial. Within six weeks of starting its regular working something occurred which prevented the requisite steam power from being furnished to the dynamo, and the gas had, therefore, to be turned on again, exactly as it had been in the former time. The result was a deputation to the manager on the part of the workmen to know what they were to do, as they could not see how to perform their work by gaslight; and on one or two occasions since then, when the light has failed through one cause or another, the workpeople have declined to work with the gas, stating that they preferred to wait until the electric light was on again, and that they could pull up the time lost.

Dynamo and Lamps.—The dynamo is of Belgian construction, and known as the four-pole dynamo. It runs at 600 revolutions per minute, and gives a voltage of 115. It is driven by a countershaft from the main engine driving the machinery in the building, and with 60 arc lamps and 66 incandescent lamps, it absorbs 70 horse-power. The lights are steady and free from flicker; if ever a lamp is seen to flicker it may be certainly concluded that it has not been thoroughly cleaned, and that the carbon slides are sticking in the magnetic brake.

Horwich Locomotive Works.—Four inverted arc lamps were tried by Mr. John A. F. Aspinall in one of the Lancashire and Yorkshire Railway work shops at Horwich, where however, owing to the great height at which they had to be fixed, they were not successful. They have since been placed in the large drawing-offices, and the light for drawing purposes is as perfect a light as can be. Failing on account of the height of the workshop to arrive at a satisfactory result with the solely reflected light, Mr. Aspinall has succeeded in lighting the main machine-shop with ordinary open arc lamps, each protruding through a white-washed disc formed of light boardings framed together. A curious combination is thereby produced of lighting by the reflected and the direct rays. It has not the whole of the advantages of the reflected light, because the eye has a tendency to glance upward towards the dazzling arcs, and shadows are projected. Nevertheless, the writer is convinced that by this combination of reflection a gain has been achieved of at least 25 per cent. over the ordinary direct arc-lighting without reflection; and all concerned are satisfied with the result.

Cost.—The question of cost of electric lighting, which after all is of the greatest importance, is somewhat difficult; and the writer is hardly in a position at present to give data sufficient to be of much practical value. Having regard to the number of workpeople who could be served with the light, the cost is less than that of gas, and of course the light is stronger and more general; so that in respect of candle-power it would be considerably cheaper than gas. In the three-storey building at the author's works there were 502 gas jets, each burning four cubic feet per hour. Gas costing 2s. 8d. per 1,000 cubic feet would, therefore, come to something like 5s. 4d. per hour for this consumption. In the 60 electric lamps the only consumption is that of the carbons, which are reckoned at one halfpenny per lamp per hour. This has subsequently been reduced considerably; but taking this basis the 60 lamps would together cost 2s. 6d. per hour for carbons. The 66 incandescent lamps which are included in the 70 horse-power absorbed by the dynamos would of course, add to this cost, as they are only 1,000-hour lamps. The greatest cost after the original installation is depreciation and horse-power. Taking the whole into consideration, it is probable that the cost of electric lighting would be more than that of gas; but as the light is so much more satisfactory, it may prove an economy in most cases to adopt it. Thus in the present instance the total candle-power of the 500 gas jets would be roughly 8,500; while the arc and incandescent lamps combined would have 73,000 c.p., much of which however is, of course, useless except for the general effect of the light.

Conclusion.—The light now described has proved in practice to fulfil the requirements enumerated at the beginning of this Paper as the necessary qualifications of a good artificial light, and for any class of manufacture for which it is applicable. For bleach and dye works, where it is necessary to distinguish minute differences in shades of colour, it must be invaluable, permitting this delicate work to be carried on in the dull winter days, which is now difficult if not impossible. If the insurance companies can be persuaded that not only is there no danger from this light, but that it is, perhaps, safer than any other mode of lighting, there seems every possibility that the use of the arc-lamp will undergo a rapid development

HEDGEHOG TRANSFORMER AND CONDENSERS.*

BY FREDERICK BEDELL, K. B. MILLER, AND G. F. WAGNER.

In this investigation a modification of the method of instantaneous contact was applied to the study of an open magnetic circuit transformer known as the "Hedgehog," experiments being made, first with the transformer under usual conditions, and then with condensers connected in parallel with the primary.

Apparatus and Method Employed.

For the complete analysis of alternating current phenomena, we should know not only the value of each changing quantity at every part of its period, but we should know the phase relations between the several varying quantities; that is, the relations between their respective zero and maximum values. To enable us to do this, the method of instantaneous contact has come into use, in which a revolving contact is made at a particular part of the period in such a way that we may ascertain the value at that particular instant of any of the varying quantities measured. The features introduced in the method as employed in the present investigation are two: first, the use of a revolving contact-maker in which the contact is made by a needle passing through a water-jet; and, second, the use of a condenser to displace the zero of an electrostatic potential instrument, so that readings are taken at the best portion of the scale.

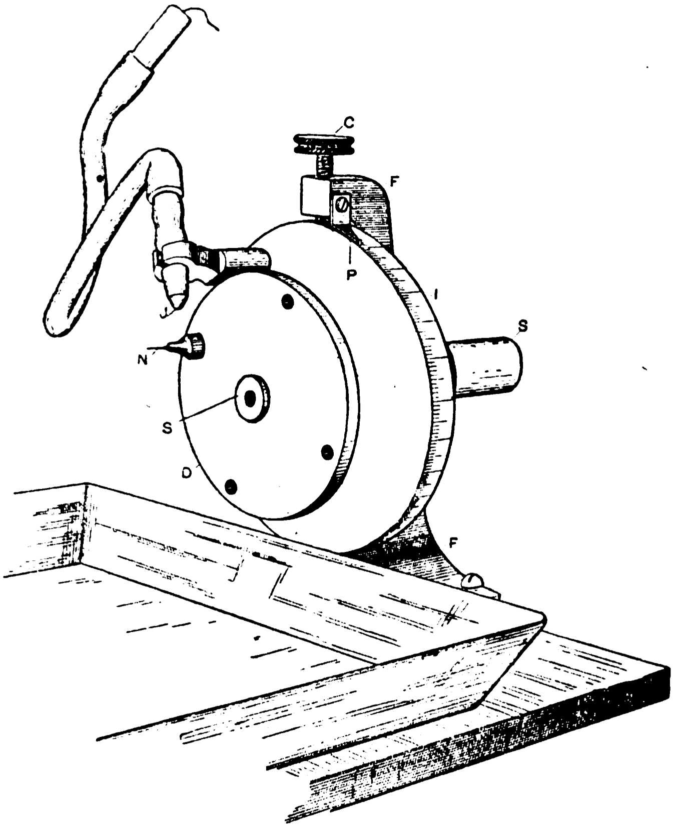


FIG. 1.—Bedall-Ryan Revolving Contact-Maker.

A general view of the revolving contact-maker is given in Fig. 1, and a detailed view in Fig. 2. The whole instrument is supported by a stationary frame, F. The shaft S is connected to the armature shaft of the dynamo by a coupling (not shown) on the end of the rod R, and carries the disc D, which revolves with it. The needle N projects from this disc and forms one of the electrodes of the contact. The other electrode is a fine water-jet (not shown) issuing from the nozzle J, well insulated by hard rubber from the rest of the instrument. This fine jet is maintained from a jar of water, several feet above, to which it is connected by a flexible rubber tube. Electrical connection is maintained with the water-jet by a wire W, which passes through this tube and is soldered to the nozzle J. Electrical connection with the needle-point electrode is obtained through the shaft and frame of the instrument. The needle cuts the water-jet once in every revolution of the armature of the dynamo, and makes a contact which is well defined and unvarying. The nozzle of the water-jet is carried upon an index disc I, which can be turned into any position by revolving it upon a projecting collar of the frame, which forms its bearing. The water-jet is held in any position by securing the index disc by

* Abstract of a Paper read before the American Institute of Electrical Engineers, New York.

Digitized by Google

means of the set screw C in the top of the frame. Its position is indicated by the pointer P, upon the scale on the circumference of the index disc which is graduated in degrees.

The needle cuts the water-jet very near the nozzle, at a point where the jet is quite stiff, due to the head of water. The nozzle is radial, and the jet keeps the direction of the nozzle for some little distance before being materially deviated by gravity. A little salt was put in the water to increase the conductivity of the jet. Pure water would not work ; acidulated water corroded the nozzle, thus changing the jet.

It was after working for some time with various mechanical contact-makers that this water-jet was devised. It came up to our expectations in every respect, the contact being perfectly constant and reliable, and free from the changes always found in a mechanical device, due to the wearing away of the contacts. This constancy is particularly necessary in an instrument which is to be used in an extended investigation, during which any change would

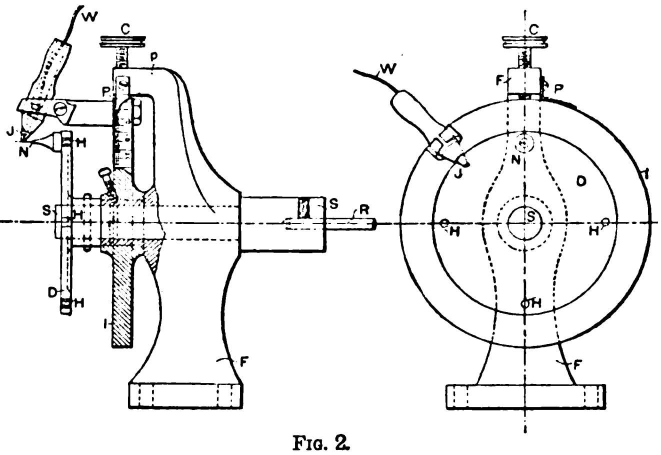

FIG. 2.

be fatal. By maintaining a fine, strong jet, for which a head of 5ft. or 6ft. is ample, and using a fine needle close to the nozzle, the instrument may be used with great precision, and needs but little attention, running every night for weeks with scarcely any interruption. Of course, the accuracy of the instrument is increased as the diameters of the discs are made greater.

For use in another investigation, in which it was desired to obtain measurements for several consecutive cycles, without interruption, the instrument was made so that the needle could be secured in the disc D, by screwing it into any of the four holes H, thus making it possible to have the contact made with the armature in any desired position, without moving the nozzle more than 45 degrees from the vertical.

This contact-maker was used with a Thomson multicellular voltmeter, as shown in Fig. 3. The difference of potential between *a* and *b* is to be measured. The condenser C_1 is kept charged to this potential to be measured, being connected through the contact-maker. The voltmeter used reads between 40 and 120 volts. Its zero was displaced by the condenser C_2, in series with it, which was

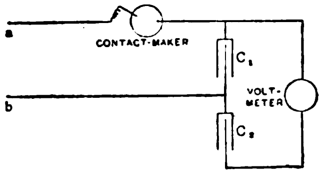

FIG. 3.

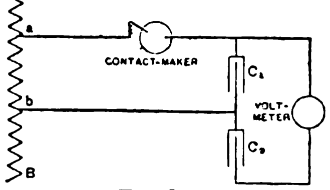

FIG. 4.

kept charged to about 80 volts ; that is, the voltmeter reading indicated the sum of the potentials of the two condensers C and C_2, so that a reading of 80 volts indicated that there was no difference of potential between the terminals of condenser C_1, or between *a* and *b* ; a reading of 85 volts indicated 5 volts difference of potential, and so on.

When a difference of potential beyond the range of the instrument was to be read, the apparatus was arranged as in Fig. 4 ; for instance, suppose it was desired to obtain the difference of potential between A and B. These points were connected by a non-inductive resistance, and the difference of potential was measured around a known portion, *a*, *b*, of this resistance, and the whole difference of potential between A and B calculated.

Measurement of current was obtained by the potential instrument in a similar way. A non-inductive resistance was inserted in the circuit, in which the current was to be measured, as in Fig. 4.

From the curve representing the instantaneous values of E.M.F. around these lamps, the square root of the mean square value of the E.M.F. was determined. The lamps were previously calibrated by a continuous current, and their resistance determined for any value of E.M.F. at their terminals. For an alternating current their resistance was ascertained from this calibration for the square root of the mean square value of the E.M.F. at their terminals, and this value of their resistance was used to obtain the instantaneous values of the current from the instantaneous values of E.M.F. in accordance with Ohm's law.

The multicellular voltmeter is ordinarily a slow instrument to read. Readings were quickened by a pneumatic damping arrangement devised by Prof. Ryan, consisting of two rubber tubes, each connected at one end to the same rubber bulb, their other ends terminating in fine glass tubes leading down through the glass cover of the voltmeter. By pumping air from the bulb through one or the other of these tubes, a draught could be produced against the needle, so as to oppose its motion and bring it quickly to rest.

The transformer upon which these experiments were made is a 60-light Hedgehog transformer, built on the general lines of an old-fashioned induction coil. A thin casting of gunmetal, cross-shaped in section, runs through its centre and supports the flanges of the spool. The four angles of this casting are filled with soft iron wires, running length-wise, thus forming a cylindrical core. These wires are considerably longer than the castings, and are spread out at their free ends, thus making a partial return for the magnetic lines. Half the secondary turns are first wound around this core, then all the primary, and finally the other half of the secondary. The primary consists of 1,426 turns of wire 0·072″ in diameter, arranged in twelve layers. It has a resistance of 2·748 ohms and weighs 29lb. The secondary consists of 73 turns of 19/0·058 cable, in two layers. Its resistance is 0·0149 ohms, and weight 12·6lb. The transformer is designed for a primary potential of 1,000 volts, with a frequency of 130.

This transformer was supplied with current from a Westinghouse alternator with a frequency of 133. The potential was kept constant at 1,154 volts by varying the exciting current. The primary E.M.F. was measured by measuring the fall of potential around a portion of a non-inductive resistance, which consisted of a series o 50-volt incandescent lamps arranged between the mains, as shown The secondary E.M.F. was similarly found by measuring the fall o potential around one of three lamps, placed in series across th secondary terminals. The primary current was found from the fa of potential around incandescent lamps, in the primary current The number of these lamps was so adjusted that the fall in potentia would be in the range of the voltmeter. The lamps were carefu ll calibrated for current at different pressures by means of a dire current, and curves drawn, from which the current could b determined for any pressure.

The secondary load consis ted of sixty 50-volt incandescent lamp mounted upon a frame in such a manner that any number of lamp could be turned on or off. It was planned to measure the secondar current by means of a calibration of these lamps, but it was foun on recalibrating them, at the end of the work, that their resistanc had increased considerably, so this method had to be abandone The secondary current was finally determined by constructing right triangle, the hypotenuse of which was equal to the primar current at no load. The third side, multipled by the ratio transformation, gave the secondary current.

To find the square root of the mean square value of the primar current, a curve was drawn, using the instantaneous values of th E.M.F. around the primary current lamps as ordinates, and second curve drawn, the ordinates of which were equal to th square of the corresponding ordinates of the first curve. Th mean ordinate of this second curve was found by a planimeter, ar its square root found. This represented the square root of th mean square of the difference of potential around the lamps. E reference to the calibration curve, the current could readily determined. Although somewhat laborious, the method proved be extremely accurate.

The square root of the mean square value of the seconda E.M.F. was measured directly by the multicellular voltmeter.

Five separate runs were made, first for no load, with the secon ary on open circuit, and then with loads of 15, 30, 45 and 60 fift volt incandescent lamps. With lamps of this resistance, the la run was quite beyond full load, inasmuch as the primary E.M. was 15 per cent. above that for which the transformer was intende The results of three of these runs are shown in Figs. 5 to 7.

At no load, the lag of the primary current is almost 90de which is greatly in excess of the lag shown by similar experime upon a transformer with a closed magnetic circuit. This diminishes rapidly as the load increases, as seen in the success curves, but it is always greater than for the corresponding load a closed magnetic circuit transformer. This is on account of t large magnetising current in the open-magnetic circuit transform the effect of this component of the total primary current being qu

Digitized by Google

marked, even at full load. The secondary E.M.F. at no load is almost opposite in phase to the primary E.M.F.; that is, it is almost 180deg. behind it. As the load increases, a small but distinct increase in this lag is noticed, due largely to increased leakage.

The power supplied to the transformer was found by finding the products of corresponding instantaneous values of the primary E.M.F. and current. These products were positive or negative, according to whether the two factors were of the same or different sign. The products thus found were plotted as curves, showing the primary power (Fig. 8), positive values being plotted above the axis, and negative below. These areas were found by a planimeter, their algebraic sum taken, and the mean ordinate thus determined.

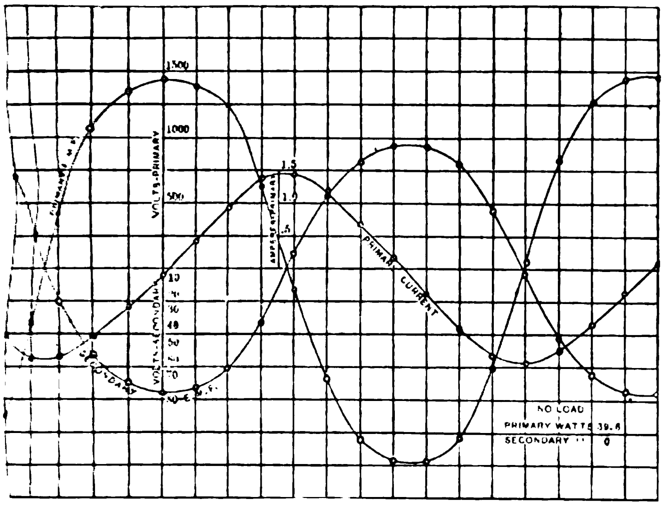

Fig. 5.

Although at no load the primary current is large, the fact that it lags so nearly 90deg. behind the primary E.M.F. causes the energy expended to be small. This was found to be a total of 39.6 watts. Of this the primary copper losses, $R_1 I_1^2$, amounted to 2.58 watts, leaving 37.02 for the core losses,—hysteresis and eddy currents. If we assume the loss in the core to vary as the 1·6 power of the E.M.F., this loss for the designed primary E.M.F. of 1,000 volts would be

$$\frac{1{,}000^{1.6}}{1{,}154^{1.6}} \times 37{\cdot}02 = 29{\cdot}4 \text{ watts}$$

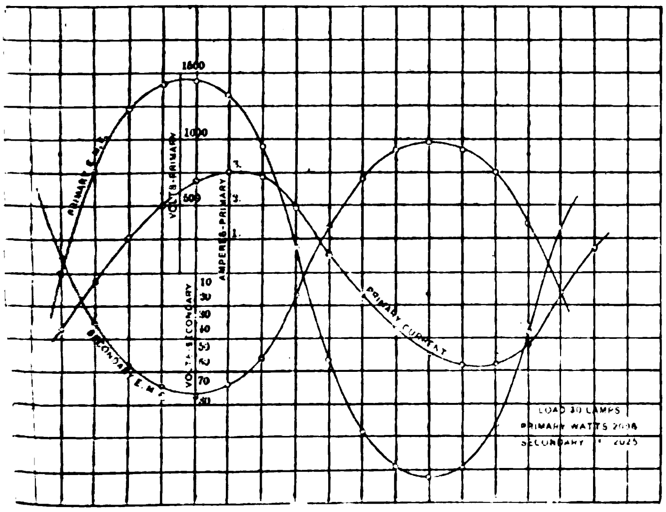

Fig. 6.

In any transformer, if the primary E.M.F. is a sine curve, the current curve would also be one, in case there were no hysteresis or eddy currents. In the no-load diagram of this transformer the primary current curve is not materially different from a sine-curve 90deg. behind the E.M.F.; while in the no-load diagrams of closed magnetic circuit transformers supplied from this same alternator, the curves for primary current depart widely from sine curves, and are much nearer the primary E.M.F. in phase. Thus the form and position of the current curve in the open magnetic circuit transformer show the hysteresis and eddy currents to be small, as compared with the transformer with closed magnetic circuit.

The efficiency of the transformer was found by taking the ratio of the secondary to primary power. The primary power was found from the watt curves in Fig. 8. The secondary power was found by deducting the primary and secondary copper losses, $R_1 I_1^2$ and $R_2 I_2^2$, and the core losses from the primary power thus found.

The curve for efficiency is given in Fig. 9, and is seen to rise very rapidly as the load increases, reaching 90 per cent. at about one-eighth of full load. From quarter load it is nearly constant, rising to 96·6 per cent. at two-thirds load. It remains practically constant until full load is reached, and then falls off slightly on over load. The all-day efficiency, calculated on a basis of five hours at full load out of 24, is 91·8 per cent.

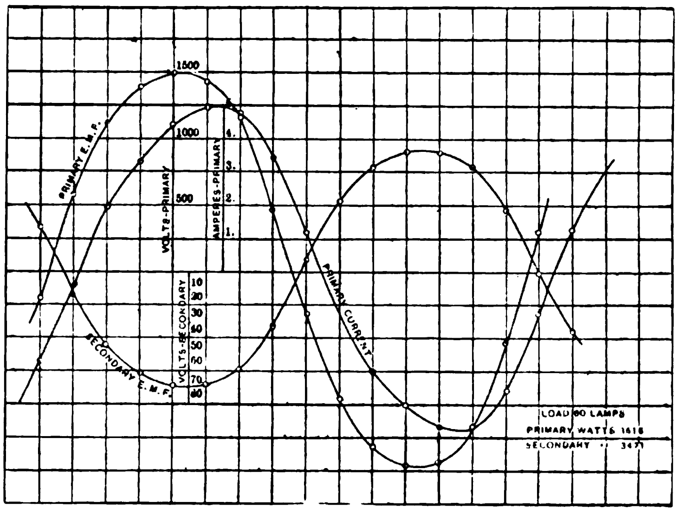

Fig. 7.

The regulation is seen by the curve in Fig. 9, showing the secondary E.M.F. for different loads. There is a fall of about 2·5 volts in the secondary, between no load and full load. This curve is drawn for a primary E.M.F. of 1,000 volts.

The primary current is shown by a curve in the same figure. Even at no load it is quite large, although representing very little energy expended. Clearly the disadvantage of such a current is that it increases the losses in the line and in the primary conductor. If this line current can be successfully reduced, one of the chief objections to the open-magnetic-circuit transformer will be removed. This can be done by the use of condensers.

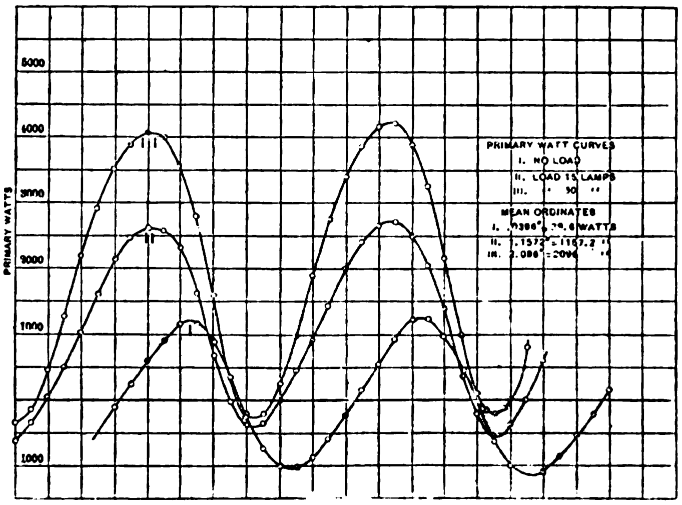

Fig. 8

Experiments were made with six condensers from the Stanley Laboratory, and were intended to be used commercially on a 500-volt circuit. The plates are of tinfoil, the useful part of which is of the following dimensions:—Length, 10½in.; width, 8in.; thickness, 0·0007in. The dielectric is of waxed paper, 0·0043in. thick. There are 65 sheets of tinfoil (total) in each slab, and two of these slabs are placed together in one tin case. The capacity of each condenser was about 1·5 microfarads. By arranging the condensers in various combinations, it was possible to obtain a number of different capacities, ranging from 0·25 to 2·25 microfarads, without

Digitized by Google

subjecting any one condenser to more than 500 volts difference of potential. The proper capacity to be used in parallel with the primary is that which will bring the line current in phase with the E.M.F. When this result is brought about, the line current is a minimum. Predetermined by an analytical and graphical method, of Dr. Crehore and one of us, the proper capacity was found to be very close to one microfarad. Fortunately, the capacity required is almost constant for all loads of the transformer. The proper capacity for the condensers was ascertained by trial as follows :— The transformer was run on open circuit with the condensers arranged in various combinations, so as to obtain different capacities, and the fall of potential around the incandescent lamps in the line was measured by the multicellular voltmeter. Square root of mean square values were obtained by direct reading, no instantaneous values being taken. This fall of potential was ascertained for different capacities, and the results obtained were plotted in a curve. The minimum drop occurs when the current is a minimum and in phase with the E.M.F. This is seen to be obtained by a capacity of almost one microfarad, the same capacity as calculated. The six condensers were therefore used, three in series and two in parallel, giving a capacity of 1·02 microfarads.

Three runs were now made, one with the secondary circuit open, and the other two with loads of 15 and 45 lamps each. Readings were taken for determining the primary E.M.F., secondary E.M.F., primary current, and line current. By primary current we mean the current in the primary of the transformer, and by line current the current supplied to the condensers and transformer together.

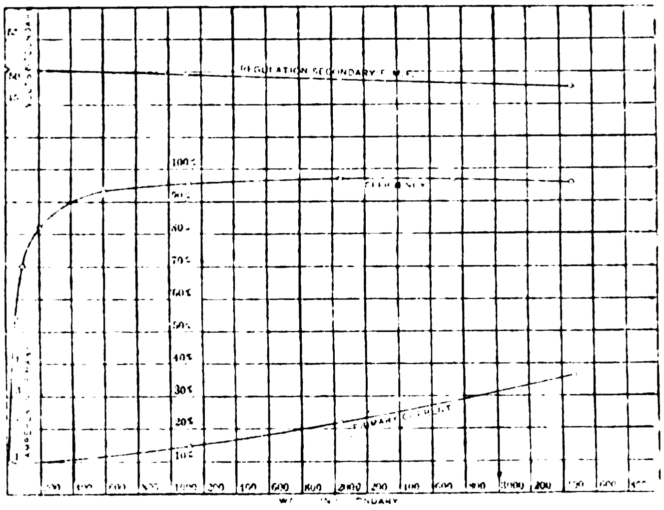

Fig. 9.

The results of these three runs are given in the following table, showing clearly the effect of the condenser in diminishing the line current, especially at no load :—

Lamps in secondary.	Primary current.	Line current.
0	0·95	0·187
15	1·24	0·867
45	3·07	2·73

At no load the line-current is seen to be less than one-fifth of the primary current, or the value it would have if the condensers were absent ; even under load the reduction is considerable.

The results of the three runs are shown in the Paper by curves. The character of the line-current curve is somewhat irregular. It is the algebraic sum (the arithmetical difference) of two almost equal and opposite currents, and is very small compared with either. If these two currents were exactly sinusoidal the resultant curve would be sinusoidal. As a matter of fact, although very nearly sinusoidal, they are not exactly so, and these variations have a marked effect upon their resultant, which is their arithmetical difference. The line-current curve has a marked depression, which brings the portion which would naturally be the crest over the axis : that is, for a brief interval in each half-period it has the opposite sign, and the current flows in a direction opposite to its flow during the other part of the same half period.

The experiments with the condensers demonstrate the practicability of their use to diminish the line-current in tranformer circuits, and points to their more extended use, as their manufacture is perfected and cheapened, not only in this, but also in other systems of alternating current distribution.

PHYSICAL SOCIETY.

At an ordinary meeting of this Society on October 27th, Prof. J. Perry, F.R.S., Vice-President, in the Chair.

Mr. E. C. Rimington read a Paper

"On the Behaviour of an Air-Core Transformer when the Frequency is below a certain Critical Value."

Taking the ordinary differential equations for two circuits having self and mutual induction, and assuming sinusoidal electromotive forces and constant co-efficients, the author shows that although the difference of phase between the primary potential difference and primary current is always diminished on closing the secondary circuit, yet under certain circumstances this closing increases the impedance of the primary. With constant potential difference this means that closing the secondary decreases the primary current, a phenomenon not usually observed. The critical conditions necessary for increased impedance are fully worked out in the Paper, as well as those under which this increase becomes a maximum. In the case of two identical coils with no magnetic leakage, the critical value of a ($a = \frac{p\,L}{r_1}$, where $p = 2\pi$ times the frequency, L the inductance of the primary, and r_1 its resistance) is $\sqrt{2}$, whilst that to give maximum impedance is $\frac{1}{\sqrt{2}}$. The maximum increase possible is 15½ per cent. The corresponding values are given for various amounts of magnetic leakage in tabular form, and curves were exhibited at the meeting showing how the impedance, current, power, and magnetising effect vary for different values of a.

To test his conclusions the author made experiments on two coils close together, the observed increase in impedance amounting to 3·2 per cent.

In addition to the analytical investigation, the subject is treated geometrically at considerable length.

Prof. MINCHIN showed that the impedances might be represented by two hyperbolas, having p^2 as abscissæ and the squares of the impedance as ordinates. These could be readily constructed from the data given. A line representing the primary inductance drawn on the same diagram intersects one hyperbola, showing that the impedance has always a maximum value. By a simple construction the phase angle between the primary and secondary currents could be determined for any given conditions.

Dr. SUMPNER observed that increased impedance on closing the secondary necessarily meant a decrease in the lag of the primary current behind the primary potential difference.

Mr. BLAKESLEY was pleased to see the geometrical method of such service, and thought it much simpler than the analytical one. The reason why increased impedance on closing the secondary of ordinary transformers had not been noticed was because their lag angles were very large. In a figure published some years ago to represent the actions of transformers the angles he had chosen were such as would make the primary impedance increase on closing the secondary. Giving an expression connecting the primary currents on open and closed secondary respectively, he now showed that to get increased impedance the sum of the lag angles in primary and secondary must exceed 90deg. To get large power in the secondary the primary lag should be nearly 90deg., and the secondary about 45deg. He also pointed out that some of the figures in the Paper might be simplified considerably.

Prof. PERRY said he had long had the impression that if a sufficiently small current were taken from the secondary increased impedance would be observable in all cases, and he quoted some numbers he had given in the *Phil. Mag.* for 1891, showing a decided increase.

Mr. RIMINGTON, in reply, said he was not aware that the effect he had now brought forward had been observed previously. The result was completely worked out analytically before using geometrical methods.

An experiment on

"Electric Radiation in Copper Filings,"

shown by Mr. W. B. Croft, was similar to those described by Dr. Dawson Turner at the Edinburgh meetings of the British Association. A battery, galvanometer, and glass tube containing copper filings, were joined in series. Under ordinary circumstances no current, passed but immediately an electric spark was produced by an electric machine many feet away, the galvanometer was violently deflected, and remained so until the tube was tapped. On trying different materials, aluminium and copper seemed about equal, but iron not so good. Carbon allowed the current to pass always.

Prof. MINCHIN said the phenomena were strikingly like those exhibited by his "impulsion cells," for the moment a spark passed, even at a distance of 130ft., they became sensitive to light. Very minute sparks were capable of producing the change, but by adding capacity to the sparking circuit the effect could be greatly modified. Replying to a question from Mr. Rimington, he said the change was due to electro-magnetic vibrations and not to light emitted by the sparks.

Mr. BLAKESLEY inquired if lengthening the sparks produced greater effect on the copper filings.

Mr. LUCAS asked if the resistance of a tube ever became infinite again left for a long time.

In reply, Mr. CROFT said the current sometimes passed before the spark actually occurred between the knobs. He had not left tubes for very long, and had not found the resistance reappear without tapping.

LEGAL INTELLIGENCE.

Fry and Francis v. The St. James' and Pall Mall Electric Light Company (Limited).

This action came before Mr. Justice Kekewich on Wednesday, the question raised being whether the Company, under its Articles of Association, was justified in carrying over from profits £1,000 in each of two years to a fund called the redemption fund, to the detriment of the Founders' shares issued by the Company. The plaintiffs (Mr. Charles Robert Fry and Col. George Edward Francis) held, the former two and the latter ten, Founders' shares, besides being Ordinary shareholders, and they sued on behalf of themselves and the other holders of Founders' shares in respect to the distribution of profits, to one-half of which they were entitled. For the year ended December, 1890, a dividend was paid at the rate of 5 per cent., a sum not sufficient to enable Founders' shares to come within the distribution; but at the end of 1891 8½ per cent. was paid on the Ordinary shares, and the holders of Founders' shares each received £10. 15s., representing one-half of the surplus profits for the year, and in 1892, beside satisfying the Preference shares, 7½ per cent. was paid to the Ordinary shareholders, and 3 guineas to each Founders' share. The Directors, however, in each of these years carried over from profits £1,000 to a redemption fund, as plaintiffs said, to the detriment of Founders' shares, and in favour of the Ordinary and Preferential shares. The point was: Were they justified in so setting aside this sum?

The case for the plaintiffs was argued by Mr. Renshaw, Q.C., and Mr. Whinnie; and for the defendant company by Mr. Warmington, with whom was Mr. Swinfen Eady, Q.C. Their contention was that there was no imputation of *malâ fides* on the part of the Directors, who had acted on the advice of the most experienced persons and in the ordinary conduct of the business of the Company. Unless their *bonâ fides* were disputed and a question of *ultra vires* was raised, plaintiffs had no *locus standi*, besides which the Directors asserted that the Memorandum of Association authorised them to act as they had done.

In the result, his Lordship said that the point raised in this case was a new one, and raised for the first time, Founders' shares being a modern invention, and not yet having attained any technical meaning. The *bonâ fides* of the Directors were not impugned, and if it were a question of internal management, according to well-known principles and decisions, the Court would certainly not interfere with what the Directors had done. They were removable representatives of the shareholders, and entitled to manage the business of the Company to the best of their ability. This was not a question of the power of the Directors, but one of contract, based on the Memorandum of Association, and he thought he was bound to hold the holders of Founders' shares to be parties to those Articles. He could not think their provisions operated to shut the mouths of holders of Founders' shares in the way suggested. If their mouths were not so shut, the accounts showed that something of the net profits of the undertaking had not been divided, and ought to have been divided. Such being his construction of the contract, he considered the plaintiffs entitled to the claim they made, and he gave judgment for them accordingly, with costs against the Company.

CORRESPONDENCE.

THE ORGANISATION OF RESEARCH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The question concerning the publication and dissemination of physical news having reached an urgent stage, it is well to bear in mind the various directions in which we may look for a solution. It appears hardly likely that the original publication of papers will become much more centralised, and if it were, the centralisation would have to be complete in order to ensure its usefulness. There are in reality two problems involved, which may be stated as follows: First, to enable physicists and those interested in physical science to obtain a fair and comprehensive idea of the work that is being done in various branches of physics. Second, to provide specialists with prompt and reliable information concerning the methods and results of those engaged in research akin to their own.

The demand giving rise to the first problem is supplied to a great extent by existing publications. But although a *Physical Review* now exists in name, there is no actual periodical representing a complete solution of the first problem. The difficulties of such a solution are obvious. We should require a physical *Review of Reviews* containing sketches of all the current contributions to the advancement of physical science, woven into a concrete image of physical progress by the pen of a physicist well acquainted with the various modern schools, and capable of interpreting their work in language familiar to the majority of his readers. I do not say that such a man could not be found; the difficulty would be to make the business worth his while.

An alternative solution consists in the publication of abstracts only, like those published by Wiedemann in his *Beiblätter* The chief drawback of the latter lies in the fact of their being published in a language not sufficiently familiar to the majority of English speaking physicists to enable them to pick out at a glance what they require. The simple translation of the *Beiblätter* into English, as advocated by Prof. Fitzgerald, would obviate this difficulty, and place at our disposal the fruits of German thoroughness. Whether such an expedient would suit the pardonable pride of British and American physicists, and whether the cost of translation, including compensation for the present English circulation of the *Beiblätter*, would fall short of that involved in starting an English periodical on some independent and original line, are questions which cannot be hastily pronounced upon.

As they stand, the *Beiblätter* represent a gallant attempt to solve the two problems together. But there is a third method, specially suited to the second problem, which has not, as far as I am aware, been pointed out yet. It is something in the way of a scientific news agency, a central office for the distribution of physical information of a specialised class to those interested in a special subject. Such an office should collect all the physical papers appearing in the four principal scientific languages, viz., English, French, German and Italian, and send out references, abstracts, or translations to its subscribers. The abstracts, &c., should appear in the language of the subscriber if the office is to be international, or in the language of the country concerned if national. It would follow as a matter of course that the extracts sent to a large number of subscribers would be multiplied by one of the numerous hectograph or mimeograph processes, or even printed in the ordinary way. Such an agency should pay its own way almost from the first, as no work would be done except that already known to be required. If it could be done in connection with one of the papers devoted to one or more branches of physics (as is *The Electrician* itself), so much the better. It would require a staff of specialists like that employed by the Chemical Society for its excellent abstracts.

In conclusion, I may mention that an International Scientific News Agency exists already in Astronomy. I refer to the Bureau at Kiel in connection with the *Astronomische Nachrichten*.—Yours, &c., E. E. FOURNIER.

October 21, 1893.

PROF. POYNTING'S STILL MORE MODERN VIEWS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have just had the advantage of reading Prof. Poynting's exceedingly interesting and suggestive "examination" of Dr. Lodge's "Modern Views of Electricity," with, I hope, equal pleasure and profit. There is one remark, however, which I should like to be allowed to make. On page 576 the "agnostic in ethereal matters" is represented as saying that "we have no sense affected by the ether alone." I have frequently heard this statement, but it does not seem to me to be in accordance with facts. What is the eye, if not a special sense organ, adapted to respond to a certain small range of ethereal vibrations, and *to nothing else*? The skin, of course, is sensitive to much besides ethereal vibrations, but it is also sensitive to these (likewise within a very small range), or how could we receive by radiation the sensation of heat? Of course, we cannot see the ether as we can a glass of water, or smell it as we can a rose, but it seems to me a mistake to say that we have no sense affected by it alone. Is it not rather that we have not been able to refer the affection to its true cause?—Yours, &c., E. M. C.

Digitized by Google

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I tried to anticipate the objection of "E. M. C." by inserting the word "alone" in the phrase which he criticises. In trying to represent the views of the agnostic it would probably have been more correct to say that "we have no sense affection which we refer to the ether alone." Certainly we refer all the energy transformations which are the physical accompaniments of our sensations to the presence of matter. If our hypothesis as to the nature of light leads us to suppose that the eye is stimulated by the ether, and by nothing else—a rather large *if*—we only mean immediately, for in tracing back the disturbance in space, we always find matter as the source from which it proceeds, and we refer our sensation to that matter. If transformations of energy occurred in materially void spaces, and if we had some sense affected by such transformations, then I imagine that this sense would give us a concept which we should call ether.

May I add a word here to say that I am very glad that Dr. Lodge thinks some of my criticism reasonable and worthy of consideration. As to the point on which we appear to disagree most strongly, probably I did not properly express the objection I have to the so-called "perfects." I do not think I shall have to re-arrange my ideas if the oxygen atoms are found to conform perfectly to the ratio 15·9, or whatever it may be, to the hydrogen atoms, are found, in fact, to be perfectly truly manufactured. What I object to is the abstraction such as we have in a "perfect conductor," where we form a conception by removing the known properties of matter. Probably I am here the victim of a hypothesis. Having come to regard a current in a conductor as essentially a propagation of some kind of strain energy into or out of a wire *sideways*, I do not see how to provide for the case of the conductor, which neither stores up nor transforms the strain energy when sent into it. There appears to me absolute difference in kind between a resistance very small and a resistance zero. I should expect the perfect conductor when found to turn out merely a non-electric, reflecting all the electrical energy incident on it.—Yours, &c.,

J. H. POYNTING.

ALTERNATE-CURRENT DISTRIBUTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Though I have already trespassed too much on your space, perhaps you will allow me to correct some misapprehensions in your reference to my letter in the current number of *The Electrician*. The 80·5 per cent. *includes* the estimated loss of 2½ per cent. on the low-pressure mains. The latter estimate is not mine. It is merely the fact, about which I was unaware there was any dispute, that with a current density of 1,000 amperes per sq. in. there is a drop of 2½ volts per 100 yards. On a 100 volt network this is a loss of 2½ per cent. Again, you say that I suggest that the sub-stations will have to improve 10 per cent. to attain an efficiency of 80·5 per cent. This is an error. I give that figure as an estimate—I believe I have shown a favourable one—for actual sub-station distribution, and while holding with you that sub-stations *may*, perhaps, do better eventually, I shall be agreeably surprised if, at present, any station engineer will come forward and prove that where the plant is running all day the company gets paid by its customers for more than 80 per cent. of the wattage sent out from the station.

When you suggest that an automatic switch is a confession of weakness, I agree that it is; it is a confession of "magnetising current," and though "magnetising current" is frequently ignored in text-books, it is unfortunately less accommodating in regard to coal-bills. It is, of course, possible, as we all know, to construct transformers taking practically no current on open circuit, but this means serious loss of efficiency when the transformer is loaded, and hence I venture to regard the automatic disconnection system as the best and most economical way out of the difficulty. I am afraid I do not share your view that complexity is necessarily an evil to any one but the manufacturer, unless it means failure in action. Mr. Tomlinson's switch, though applicable only to sub-stations, is decidedly more complex than the other you described in your issue of June 9th, as intended for use with separate transformers. In conclusion, I would suggest that as the "up-keep" (waste on open circuit) can easily amount to £12 per annum, even with a 2½-H.P. transformer, and as it is the companies who sustain this loss, it is naturally they whom one would expect to be inclined to pay for an appliance by which it may be avoided.—Yours, &c.,

October 30th. R. N. LUCAS.

PRIMARY BATTERIES IN THEORY AND PRACTICE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Aylmer has called my attention to an error which appears in my Paper on Primary Batteries (*The Electrician*, October 27, p. 695), and which I should be glad to correct. Referring to the Leclanché dry cell, I stated that it is only necessary to pour some water into the cell in order to renovate it, in the event of its becoming too dry. This is, however, incorrect. A solution of sal-ammoniac, or other suitable compound, must be employed for this purpose.—Yours, &c.,

W. R. COOPER.

Woodlands, Clapham Park, London, S.W.
October 28, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES' DIRECTORY AND HANDBOOK" contains over 1,000 pages, several new and handy features having been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

The 1894 Edition is in preparation, and will be published in January next. New names, alterations of addresses, &c., are received at any time, but the Directory blanks and circulars are not sent out until later in the year, in order that the most recent, and consequently the *correct*, addresses *only* shall appear in the book. Full printed particulars can be obtained, post free, from "The Publisher," *Electrician* Office.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, which has a special interest at the present time, will be ready next week, and will be forwarded on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus can be obtained on application to the Publisher.

TENDERS INVITED.—The Corporation of Sunderland, it will be seen by our advertisement columns, invite tenders for the supply, in connection with their scheme of electric lighting, of (1) boilers; (2) engines, dynamos, pumps, steam-pipes, &c.; (3) motor alternators, switchboard, &c.; (4) main switchboard, instruments, and connections; (5) batteries; (6) insulated cables, &c.; (7) supplying and laying culverts, &c.; (8) copper strip; and (9) gunmetal grip boxes. Persons or firms wishing to tender for any of the above contracts must send their names and addresses to the Borough Engineer, Town Hall, Sunderland, from whom drawings, specification, and forms of tender are to be obtained. Tenders must be addressed to the Chairman of the Highways Committee, and be sent in to the Town Clerk's Office, Sunderland, on or before Friday, November 17th.

——— The Electric Lighting Sub-Committee of the Corporation of Newport invite tenders for the supply and erection of engineering and electrical plant and apparatus for the equipment of the Municipal Electricity Works of the County Borough of Newport. The plan of buildings, map, specifications, &c., can be obtained at the offices of Mr. Robert Hammond, consulting engineer to the Corporation, 117, Bishopsgate-street, London, E.C.; and tenders must be addressed to Mr. Albert A. Newman, Town Clerk, the Town Hall Newport, (Mon.), not later than Monday, November 20th. Further particulars are given in our advertisement columns.

——— The Gas and Lighting Committee of the Bolton Corporation invite tenders for the supply and erection of switchboards, accumulators, connections, &c. Specifications, &c., can be obtained from Mr. J. H. Rider, the borough electrical engineer, and tenders must reach Mr. Alderman Miles, chairman of the above committee, at the Gas Office, Bolton, not later than Saturday, November 18th. Further particulars appear in our advertisement columns.

Digitized by Google

TENDERS INVITED.—The Corporation of Dewsbury invite tenders for the work required in the erection of an electric lighting station within the borough. Plans may be seen at the office of the Borough Engineer, from whom specifications, bills of quantities, and forms of tender may be obtained. Tenders are to reach Mr. E. Mawdesley, the Town Clerk, by the 17th inst.

——— The Municipality of Mahon, Spain, invite offers for the electric lighting of the town. Particulars may be obtained from the Ayuntamiento Constitucional of Mahon, and tenders must be in by November 16th.

——— The Cheshire Lines Committee invite tenders for General Stores and Permanent Way Materials, including telegraph materials, instruments, wire, &c. Tenders must be in by 10 a.m. on December 2nd.

PERSONAL.—Dr. W. E. Sumpner has been appointed head of the electrical department of the Battersea Polytechnic.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty announce a sale by auction on November 17th, on the premises of the Vulcan Iron Works, situated at Beccles, Suffolk, together with freehold land and buildings. A large quantity of plant and machinery is for disposal.

LIQUIDATIONS.—On Thursday last week a petition came before Mr. Justice Vaughan Williams for the winding-up of the Ipswich Electricity Supply Company, which, however, was adjourned for a week.

——— A petition has been presented by Mr. Thomas Brooks Browne, advertisement contractor, for the winding-up of the Medical Battery Company (Limited), and is down for hearing on the 8th inst.

——— Mention was made before Mr. Justice Vaughan Williams last week of a petition for the winding-up of the Wrexham and District Electric Supply Company (Limited); but leave was asked for the petition to be withdrawn, which was granted.

——— The shareholders of the Steam Loop Company (Limited) have decided to voluntarily wind up the Company.

——— A meeting of the members of the Maquay Syndicate (Limited) is to be held at Mr. Thomas Rawlins's, 45, King William-street, E.C., on November 18th, at noon, for the purpose of receiving the liquidator's account of the winding up.

——— Mr. Frederick Samuel Lucey, of 3, Bucklersbury, E.C., has been appointed official liquidator of the International Cable Company (Limited), in the place of Mr. John Lord, deceased.

WILFUL DAMAGE.—The man M'Queen, who, as mentioned last week, was charged at the Manchester Police Court with wilful damage at the Mosley Hotel, by pulling a fuse out of its socket, causing the electric light to suddenly go out, was, with another man named Bridge, charged with a similar offence at the same time, sentenced on Tuesday to a month's hard labour.

BANKRUPTCY.—A first and final dividend of 2s. 4½d. in the £ has been declared in the estate of Austin Herbert, formerly carrying on business as an electrician at St. James-street, Nottingham.

DISSOLUTION OF PARTNERSHIP.—Notice is given of the dissolution of the partnership between James Robert Fawkner and Henry John Rogers, carrying on business at 10, New Bridge-street, E.C., as engineers and contractors, under the style of Fawkner, Rogers, and Co. All debts to and from the firm will be received and paid by H. J. Rogers.

AWARDS.—Mr. Frederic Nell informs us that the Victor Turbine has been awarded a first prize gold medal at the Chicago Exhibition.——Messrs. Doulton and Co., of Lambeth, London, S.E., have obtained six highest awards for their various manufactures exhibited at the Chicago Exhibition.

EXHIBITIONS.—There is to be an International Confectioners', Bakers', Grocers', and Biscuit Manufacturers' Annual Exhibition at the Agricultural Hall, Islington, London, N., from November 4th to the 11th, at which the machinery used in the various trades represented is to be shown working.

AGENCY.—Messrs. Paterson and Cooper inform us that they have been appointed agents for the United Kingdom for the sale of Messrs. Richard Freres' electrical and industrial measuring instruments.

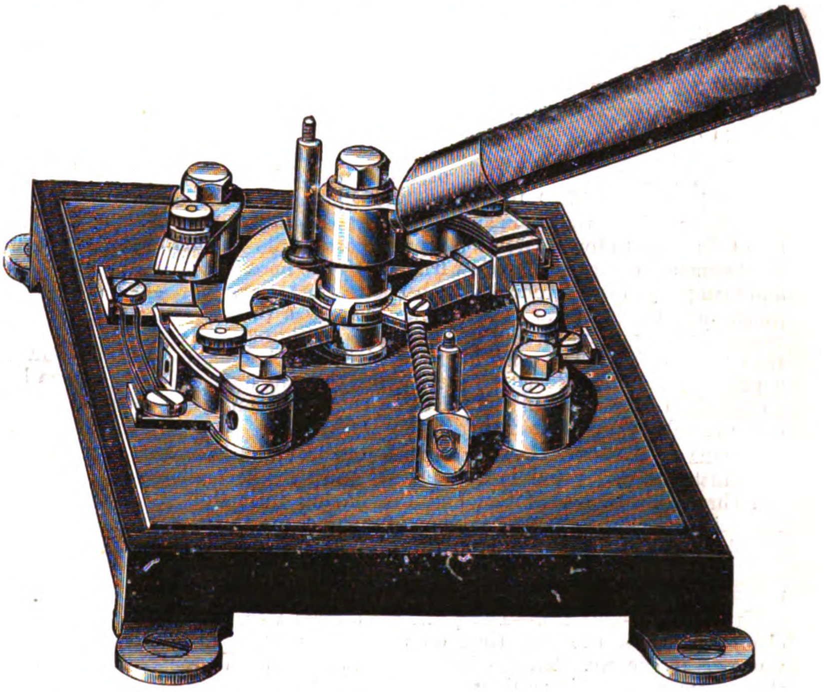
A NEW TRAMCAR.—Major-General Hutchinson, R.E., recently inspected on behalf of the Board of Trade, the Lührig tramcar, which is about to be used on the Croydon and Thornton Heath section of the Croydon and Norwood Tramways Company. The new car is a German invention, and is propelled by means of gas. It is self-contained, and has a running capacity for about 15 miles. Refilling takes place in rather over a minute through an ordinary india-rubber delivery hose connected with a nozzle in the body of the car. There is no smell or vibration and very little evidence of the waste gas going into the atmosphere. From experiments made by Prof. A. B. W. Kennedy, F.R.S., it is expected that in ordinary circumstances the cost of traction will be reduced by about 65 per cent. The gas is ignited by an electric spark, and the motive power, which consists of two double-action I.H.P. gas engines, is completely hidden, together with the fly-wheel, at the back of the seats. Major-General Hutchinson expressed his approval of the car, and passed it, subject to the carrying out of certain minor alterations.

"MECHANICS."—This is the name of a new journal, to be published monthly, commencing with the new year, price 3d. Amongst the advantages claimed for it are that there will be "no algebraic equations, no mysterious diagrams, and no abstruse theories."

ELECTRICAL FITTINGS.—Messrs. Wm. McGeoch and Co. have just issued a new fully-illustrated catalogue of electrical apparatus manufactured by them, of which stocks are kept at London, Glasgow, Birmingham, and Sunderland. A variety of switches, cut-outs, ceiling roses, lamp-holders, globe-holders, ball and counterweight fittings, standards, brackets, &c., are included in the catalogue.

ANTI-FRICTION METALS AND TIN ALLOYS.—Messrs. Höveler and Dieckhaus send us particulars and prices of their white anti-friction metals and tin alloys, for which they have obtained a first prize (medal and diploma) at the Chicago Exhibition.

THE "COMPANY'S" SWITCH.—Messrs. Verity and Co. have shown us a specimen of their double-pole switch, especially intended for



use as the main switch for houses connected to supply systems. It has a quick make-and-break, and appears to be well adapted for its work. The handle is easily removable.

ANTI-SULPHURIC ENAMEL.—Messrs. Griffiths Bros. and Co. inform us that their anti-sulphuric enamel is being employed at the large central station at Brussels for the protection of the metal and woodwork from acid fumes.

MESSRS. DRAKE AND GORHAM.—This firm inform us that, owing to their constantly increasing business, they have found it necessary to provide additional accommodation for their staff.

ABERDEEN.—The Lighting Committee of the Corporation have decided, in order to give an idea of the effect of the electric light in the streets, to light a small area of the city in advance of the general scheme.——A deputation of the Corporation recently visited the principal watering places in England and France, with a view of drafting a scheme for the establishment of a new bathing station on the beach. Their proposed scheme includes an esplanade, with a pavilion for entertainments, and an electric tramway from Castle-street to the proposed esplanade. The scheme is to come before the Town Council at their next meeting.

AGRICULTURAL HALL.—At last an attempt is being made to light this huge building by electricity. We learn that 40 of the Electrical Company's "Luna" arc lamps have been supplied for

Digitized by Google

lighting the main hall, the current for which is generated by a Brush high-tension dynamo, driven by a 50-H.P. Stockport gas engine. The installation has been carried out by Messrs. Vaughan and Brown.

BRIGHTON.—Mr. J. T. Chappell, the contractor who had in hand the extension of the Corporation Electric Lighting Station in North-road, recently failed, and the work was consequently at a standstill. The Works Committee, however, instructed the borough engineer and surveyor to take possession of the works and the materials, plant, &c., in use for the same, and the extension is being carried out under the direct control of the Corporation.

CAMBERWELL.—A special meeting of the Vestry is to be held on December 6th for the purpose of considering the advisability of applying to the Board of Trade for a Provisional Order. At the last meeting an Electricity Committee was appointed.

CONCERT.—A smoking concert will be given this (Friday) evening by the Telephone Athletic Association at the "Haunch of Venison," Bell-yard, Temple, E.C., to commence at 7.30 p.m.

DEWSBURY.—The Local Government Board has sanctioned the borrowing of £25,000 for electric lighting purposes, and have also approved of the use of the site of the old gas works at Battle Carr for a central station.

EALING.—Mr. Codrington, one of the Local Government Board inspectors, held an official inquiry on Thursday last week with reference to the application by the Local Authority for permission to borrow £25,000 for the purpose of electric lighting.

GOVAN.—The Govan Combination Parochial Board have had estimates submitted to them for the lighting of the new asylum at Hawkhead, showing that electricity would cost £635 per annum, oil gas £282, and Glasgow Corporation gas £200. The Board have decided to adopt the latter.

H.M.S. "HOWE."—In connection with the refitting up of this battle ship, the Dockyard authorities at Chatham being unable, owing to the limited time available, to undertake the renewing of the electric light and gun-fire circuits, the work was entrusted to Messrs. King, Brown and Co., of Edinburgh. The "Howe" is lighted by means of 520 16-c.p. incandescent lamps, in addition to the usual yardarm reflectors and semaphore signalling lamps, cables also being laid to four search-light projectors, while the gun-firing arrangements comprise electric wiring, with the necessary batteries and firing keys for the four 63-ton barbette guns, the six broadside guns, and five torpedo tubes. The work was carried out continuously day and night, and was completed within ten weeks from the date of order. The experiment of placing such a contract with a private firm has proved so satisfactory that we understand the authorities contemplate taking the same course in connection with other vessels at present refitting in the Dockyard.

HOWRAH (CALCUTTA).—The scheme for providing an electric light installation for public and private purposes seems likely to fall through, Messrs. Martin and Co. having intimated to the Municipal Commissioners that they cannot accept the terms proposed by the latter, whereby the plant would become their property after 20 years, which period would be too short for the firm to recoup themselves for their outlay.

KINGSTON-ON-THAMES.—The principal streets were lighted with electric light for the first time on Wednesday. The installation was a great success. Thirty-six arc lamps have been erected in the streets, each having a lighting power equal to 100 candles, displacing 75 gas lamps. The Town Hall, Municipal Offices, Free Public Library, and several shops and private residences are also lighted by electricity. The contract was carried out at a cost of £16,000. A formal inauguration ceremony will take place to-morrow (Saturday).

LAMBETH.—The Crystal Palace District Electric Supply Company have informed the Vestry that they intend to apply to the Board of Trade for a further Provisional Order under the Electric Lighting Acts.

LECTURE.—Mr. Whitehouse, instructor in telegraphy at the Municipal Technical Schools, Birmingham, delivered a lecture on Monday last on the phonopore. The lecturer was listened to with marked attention by a large audience, and at the conclusion he received a vote of thanks.

LLANDRINDOD WELLS.—The Local Board after consulting with a firm of electrical engineers, have decided to apply to the Local Government Board for a Provisional Order to enable them to supply electricity.

LYNTON.—The Local Board, having declined to purchase the electric lighting plant from Mr. Benn, that gentleman has intimated his intention of applying to the Board of Trade for a Provisional Order.

MONMOUTH.—A special meeting of the Town Council was held on Friday, when the plans for a new drainage system for the borough, combined with electric lighting, were approved. The scheme and plans have been forwarded to the Local Government Board for approval, with an application for powers to borrow £18,000 for the purpose of carrying out the scheme.

PENRITH.—The Local Board of Health have resolved to apply to the Board of Trade for a Provisional Order for electric lighting.

PONTARDAWE.—Messrs. W. Gilbertson and Co. (Limited) have applied to the Board of Trade for a licence to light certain streets in Pontardawe with the electric light.

PORTSEA ISLAND.—The Board of Guardians have decided to have their offices in St. Michael's-road lighted by electricity.

SALFORD.—The Corporation recently sought to obtain powers from the Local Government Board to borrow £50,000 for electric lighting purposes. The Board, however, have sanctioned the borrowing of £32,000 for this purpose, repayable within twenty-five years.

SIAM.—The *Rangoon Gazette* of September 11th, in the course of an article on "Public Works and Companies in Siam," alludes to the Bangkok Tramways Company (Limited). The line is six miles long, and one-half the distance has been equipped with electrical plant by the Short Electric Railway Company, of Ohio, on the overhead wire system, at a cost of £6,500. The electric cars had only been running a few weeks, and it was consequently impossible to form any just comparison of the working cost of electric traction with that of the superseded horse traction, but it was estimated that a saving in the working expenses of over £30 a month would be effected. Should this prove correct, the entire line would shortly be worked by electricity. Reference is also made to the Siam Electric Light Company, which got into difficulties at the beginning of 1892, just when they were about to start lighting. The plant and apparatus were supplied at a cost of £45,000, £15,000 of which was disputed, and an arbitration resulted in the amount being reduced to about £13,000. The Company, however, found themselves unable to raise any more capital, and the Government, to prevent any difficulty, took over the whole concern for £20,000, paid all creditors at once, and were then in possession of a first-rate electric lighting plant for less than half the cost price. Nothing, however, has since been done, and the valuable machinery has been idle for six months, and there is apparently no present intention of starting the works.

STIRLING.—It was stated at a meeting last week that an electric lighting company were prepared to light the town, and to buy up the Stirling and Bridge of Allan Tramway Company, so as to work the cars by electricity. The light was to be supplied at a cheaper rate than gas, and the adoption of electricity for the tram-cars would, it was said, enable the Company to charge only half the present fares.

ST. HELENS.—The Gas and Lighting Committee of the Corporation have resolved to apply to the Board of Trade for a Provisional Order to supply electricity.

TAUNTON.—The purchase of the electric light works by the Town Council was finally completed at the meeting last week, when cheques for the amount of the purchase were drawn, and the transfer completed.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS.

Eastern Extension, Australasia and China Telegraph Company (Limited).

The fortieth ordinary general meeting of this Company was held on Wednesday at Winchester House, Old Broad-street, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. F. E. Hesse) read the notice calling the meeting, and the minutes of the previous meeting, which were approved by the present meeting and signed by the Chairman as correct.

The report of the Directors having been taken as read,

The CHAIRMAN said: I will go over some points relating to our proceedings during the past six months, in order that you may have a little more information than the report has afforded you. The gross revenue for the half-year under review—to June 30th last—has amounted to £257,986, against £246,988 for the corresponding period of 1892, showing an increase of £10,998. The working expenses have amounted to £78,229, against £79,281 for the corresponding period of 1892, showing a decrease of £1,052. The usual interim dividends, at the rate of 5 per cent. per annum, have been paid for the past half-year, amounting to £62,500, and the balance of £81,116 has been carried forward, as against £70,271 for the corresponding period of 1892. The second year of the Australian tariff guarantee arrangement expired on April 30th last, when it was found that the loss for the year had amounted to £43,558, as compared with £55,040 for the first year of the guarantee. One half of this loss, or £21,779, has been made up by the guaranteeing Governments, and the remainder has been distributed between this Company and its partners in the "pool" as follows:—Eastern Extension Company £14,069, Eastern Company £6,208, Indo-European Company £925, and the Persian Gulf department of the Indian Government £577. During the current or third year of the guarantee the loss will, as far as we can at present judge, be comparatively nominal, owing to the additional 9d. that was added to the tariffs at the request of the Colonies having come into force on January 1st last, and to the abnormally large traffic that was carried a few months ago, when the bank reconstruction schemes were being arranged. You have heard a good deal about the New Caledonia cable. That cable has now been laid by the French company to which I referred at the last meeting. It has received from the Queensland Government a small subsidy of £2,000 a year, and a similar subsidy has been received from the Government of New South Wales, while the French Government have given a guarantee of £8,000. Its promoters have claimed for it that it is the first link of the much-talked-of Pacific cable between Australia and Canada, but after the strong opposition displayed to it both in the Colonies and on this side, it is not likely to be anything more than a local line, and as a local line it will be rather a "feeder" to us than a competitor. As to carrying this line through the Pacific at the present moment, there is no earthly use for it, and if one may judge from the financial position of the respective Colonies, they are not likely to spend money for an object which they have already attained, namely, a reliable service. Governments do not go into transactions of this kind for the purpose of losing money, and if they were to endeavour to introduce any such system in opposition to commercial enterprise, I am perfectly sure that they would not have the sympathy of either England or of their own Colonies. It might cheapen the tariffs a little, but I think that with the position we occupy now—not only through our reserve fund, which is large, but also through our financial arrangements with the Colonies—they are not likely to become parties to any large amount in any such arrangement. The Governments of Queensland and New South Wales have already been called to account for what they have done, and if I may judge from the tone of our own Government and the feeling here, I think this matter is not likely to go further for a very long time to come. When another system is required for connecting the old country with the Australian Colonies you may depend upon it that we shall have a finger in the pie (applause). I will now refer to a subject which should be a lesson to those who aspire to lay cables. It is also a satisfactory matter to us that, having looked so far ahead, we have been able to avert what might at the present moment have been a very serious state of things indeed. Only last week both our Port Darwin cables became interrupted within a few hours of each other, many hundred miles apart, and but for our third cable to Western Australia the Colonies would have been entirely cut off from telegraphic communication. Fortunately we had a repairing vessel available close by, and within a few days we hope that both cables will be repaired (cheers); but similar troubles arising from inequalities of the bottom and coral landing places would most certainly occur in the Pacific, making it absolutely necessary to provide a duplicate line, with at least two maintenance ships, and a large sinking fund, which would require to be got out of earnings, to replace the cable within a reasonable period (hear, hear). I think that that will show you that those who do not know much about cables—if they will benefit by the experience of those who possess such knowledge—should think twice before they spend money upon a new system when there is a thoroughly good service already in existence that can do all the work that is required (hear, hear). At the last general meeting reference was made to negotiations that had been in progress for a good many years for strengthening the China section of the Company's system. I may tell you that for the last 10 years we have been working, not only with the Colonial Office here, but with the Straits and Hong Kong Governments, on the subject. We endeavoured to obtain from them a concession with some subsidy for the work we proposed to do. We have one cable there, and it is a very valuable link as far as it goes; but I have just shown you that our experience clearly points to this—that where commerce is being based, as it is now, on telegraphic communication, a single line is not sufficient to

Digitized by Google

maintain the regularity of such a system. We have nearly duplicated the whole of our cables, and we have endeavoured to duplicate this line that I am now referring to by obtaining from the Government advantages which we thought we were entitled to. We have not succeeded in getting money, but within the last two days we have signed and sealed an agreement which will justify us in laying another cable from Singapore to Hong Kong, connecting en route Labuan, near to British North Borneo, which has hitherto been without telegraphic communication with the rest of the World. If we have not got money we have obtained certain privileges and advantages, of which I am not prepared to tell you all the details to-day, but of which by-and-by you will know something more. I think, however, that I may say this—that what we have obtained will be quite as valuable, if not more so, than if we had got the money we originally asked for (applause). You will have seen in the report the allusion made to the loss we have sustained by the death of our esteemed and valued colleague, Sir James Anderson, who, as you know, was connected with this Company from its inception. As an old sea captain he knew a good deal about the details of ships and cables, and he was altogether a most excellent and valuable colleague. As an old friend of his I need not say that I feel his loss very much; but I may also add that we have now placed our system upon such good foundations that with careful attention and the oil that is necessary to be applied to the working of any great machine, it will run perfectly smoothly, so that we may continue to occupy the proud position which we now hold and upon which we may all congratulate ourselves (applause). I believe there are very few chairmen who have had of late the opportunity of submitting to their shareholders, as I have done to-day, such a very satisfactory report on the past six months' working, and you may well be proud of it (hear, hear). This is not the bonus period; that will be at the end of the next six months. Meantime, I can assure you, without any hesitation, that the system is being worked now in as satisfactory and prosperous a manner as it has been at any period of our existence. The vacancy that was caused by the death of Sir James Anderson has been filled by the appointment of Sir Albert J. Leppoc Cappel, K.C.I.E., late Director-General of the Indian Government Telegraphs, to a seat at the Board. The experience of Sir Albert Cappel during his long residence in India, and his connection with the telegraph system there, was his qualification for joining this Board, and I may tell you that in making these appointments we act with the view of giving the utmost strength and stability to our telegraphic system. You will have also seen from the report that in consideration of the ever-increasing duties and responsibilities devolving on the management, and to the fact that the duties of Managing Director have been performed by myself without salary ever since the death of Col. Glover twelve years ago, the Board have thoughtfully—and I might almost say wisely—proposed, as I have performed the duties, to add to my remuneration the salary that used to be paid to the Managing Director (cheers). I am very glad to hear that indication of your approval, because in my quarter of a century's connection with submarine telegraph cables it has been my experience generally—not so much in the last ten years, but previously—that the great aim and object of these meetings was apparently to cut down Directors' fees (laughter). But I must tell you plainly that if you want good men—men who have brains to apply to the work, time to devote to it, and who have ambition to make what they are attending to a marked success, you cannot pay them too well. I do not believe there is a single Director who sits here for the purpose of simply earning his fees, but we all know the value of money. We know that time is money, and where men give up their time to work like this, and make it as marked a success as we have done, I think they ought to be paid well, and I am pleased to find that the shareholders approve of such action as that which I have just mentioned. I think I have now given you probably as much information as it is in my power to give you to-day with respect to the last six months' working of the Company. I hope that by the time I meet you again our duplicate China cable will have been laid, and that I shall be able to tell you that we stand in a position not only satisfactory to the public generally, but equally satisfactory to the shareholders also (applause). With these remarks I beg to move

"That the report and accounts of the Directors now submitted be received and adopted."

The Most Hon. the Marquis of TWEEDDALE: I beg to second that motion.

The CHAIRMAN then expressed his readiness to answer any question which the shareholders might desire to ask, but no one rising to address the meeting, he put the motion in the usual way, and having declared it carried unanimously, added: That is the whole of our business to-day.

Mr. GIVENS thought that the shareholders should not separate without offering a hearty vote of thanks to the Chairman and Directors for the admirable way in which they had managed the business of the Company hear, hear). He concluded by moving a resolution to this effect.

Mr. CLAY seconded the motion.

Mr. H. T. BURGESS, in supporting the resolution, said he thought the shareholders would be very much wanting in gratitude were they not to recognise by a hearty vote of thanks the splendid management of the Chairman and Directors (applause).

The resolution was thereupon put to the meeting and carried unanimously.

The CHAIRMAN: I am very much obliged to you, and I thank you on behalf of my colleagues and myself for what I may call a full and fair recognition of the Directors' services. As I have said before, I think the more that confidence can be established between the shareholders and the Board, the more satisfactory and prosperous the Company will be. That has been our policy throughout; it will continue to be our policy, and I hope I shall always be able to show you such good results arising from that policy as I have done to-day (hear, hear).

The proceedings then terminated.

Aluminium Company (Limited).

The sixth annual ordinary general meeting of this Company was held at the Cannon-street Hotel yesterday, under the presidency of Mr. Gerald W. Balfour, M.P.

The SECRETARY (Mr. G. H. Clarkson) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN, in moving the adoption of the report and accounts, said that the misfortunes and disappointments of the Company had been so often referred to at their previous meetings that it was a double pleasure for him to come before them on that occasion with words of encouragement and hope. The tide had indeed begun to turn when he last addressed them, but during the financial year which preceded their last meeting the trading account still failed to exhibit a profit, although a great improvement was shown. On the present occasion, however, they were able to announce a trading profit of £7,000, and that was not all. Their business had been, and was, a growing one. In the first four months of the financial year they were now considering—that was to say, June, July, August, and September, 1892—they did not make any trading profit, but a loss of £2,500, which was owing, however, to very special causes. During the following eight months, on the other hand, they made a profit of about £10,000, and their average daily output for this period was 2½ times greater than it was during the first four months in which they incurred the loss of £2,500. Further increases had since been made, and their average daily output at the present time was 4½ times what it was during the first four months of the year under review. Assuming, therefore, as they were entitled to do, that the trade profits would be increased in proportion, they were now making at the rate of over £25,000 a year. During the last few months they had granted a licence to one of the most important chemical firms in Germany to manufacture under their patent. The plant would be at work in a very short time, and the royalty payable under their licence would go to increase their profit. Deducting from the trading profit mentioned their fixed charges of £10,000, of which £7,000 represented debenture interest, the sum of £15,000 would be left to provide for depreciation and dividend on the "A" shares. This was assuming that the proposals which the Directors made for reducing the capital were accepted by the shareholders. Their present success had been achieved in the face of great difficulties, the nature of which might be understood when he stated that at the present time there was hardly a single one of the processes with which they started still in use at Oldbury. In fact, the title of the Company had become a misnomer, since they no longer produced aluminium. They had developed the trade in sodium, partly by finding new uses for it, and partly by reducing the cost of production. They had made contracts with all the principal users of sodium over a considerable number of years, and there was not very much fear that they would be exposed to competition even—which they did not think at all probable—if someone were to invent a process by which sodium could be made and sold profitably at their present price. One material which they manufactured—peroxide of sodium—was a completely new commercial product; they already had a large business in it, and it was showing signs of being likely rapidly to increase. In fact, he thought it was not too much to say that peroxide of sodium would probably eventually supersede all other bleaching materials in certain particular lines. The change of front which they had been obliged to execute had not been made without heavy loss, and it had long been evident that they would have to write down their nominal capital very largely. They had, however, felt that it was useless to take this step—the operation involving a large amount of expense—unless and until their doing so would be likely to make a dividend possible. In the opinion of the Directors this time had now arrived. He wished to point out that the writing down of the capital could not possibly affect the real value of the Company's property, but what it did influence was the power of the Company to pay a dividend. Unless they wrote down their capital they would be unable to divide a penny of dividend until they had made good their losses, and if the shareholders desired to see any immediate return on the money they had invested in the Company it was absolutely necessary for the capital to be written down. They might say, perhaps, that it was rather a drastic measure to reduce the capital as the Directors proposed, from £5 a share to £1 a share, but he would remind them that it was impossible for them to write down their loan capital, which, however, they expected to be able eventually to get rid of altogether, when the market value of their shares would rise in proportion. With respect to the new electro-chemical process invented by Mr. Castner, the matter was referred to at their last meeting, when, however, a careful reticence was observed with respect to the character of the process. The causes for this reticence no longer existed, and he might tell them that the process was for the manufacture of caustic soda and chlorine direct from common salt by electrolysis. The manufacture of caustic soda and bleaching powder was one of the most important chemical industries in the country. He was expressing the opinion of great authorities when he said that all processes now in use for the manufacture of these materials must give way to an electrolytic process, and they believed that they were first in the field with an electrolytic process which was of a thoroughly satisfactory character. All the hopes which they held out at the last meeting as to the value of this process had, they believed, been amply realised. It was a process that turned out the material in a state of chemical purity—a thing unknown to commerce up to the present time, and they believed that it could be produced at a very much lower price than at present. Those who were concerned in electrical processes might be interested to hear that the process he was referring to reached an efficiency very close to the margin of what was theoretically possible, and therefore he did not see that any invention of a similar kind was likely to improve upon it. The process was in work at Oldbury not on a miniature scale, but on a scale which would be employed in actual practical manufacture, and there was nothing now experimental about it, except in so far as they might gather further information regarding the amount of wear and tear caused by long and continuous running. Their experience during the past year

in working this process had been most valuable, and it had resulted in their filing two additional patents in connection with it, and this, of course, added very materially to the strength and the value of the original patent. The Directors believed that the process was one of extreme value, and their hope—for which they had good grounds—was that ultimately it might be the means of returning to the shareholders a considerable amount of the capital which it was now proposed to write off.

Sir HENRY E. ROSCOE, M.P., F.R.S., in seconding the motion, referred with satisfaction to the improvement in the position of the Company. The demand for the sodium and the peroxide of sodium which they manufactured has been increasing, and there was every prospect of this continuing. They were greatly indebted to all who were connected with the works at Oldbury, and especially to Mr. Castner, for the efficient manner in which the two processes were carried on. The new process referred to by the Chairman originated in an endeavour on their part to prepare a pure article of caustic soda. The reason they started the new process was to enable them to manufacture sodium at a cheaper rate than they could do with the article on the market, which was the only article they could purchase. From that grew up the larger view of the question referred to by the Chairman, whose statement he could endorse that in future the mode of making this most important article—which was now made not by the ton, but, perhaps, by hundreds of thousands of tons—would be by a process similar to that which the Company now had in hand The question was, How far their process was the one that would be worked? and all they could say was, from what they knew of other proposals as well as their own, that they believed theirs would hold the field. On that point, however, they would know more at their next meeting.

A short discussion followed, and in answer to questions,

The CHAIRMAN stated that the "B" debentures had in no way impaired the securities of the holders of the "A" debentures. They sold their material as rapidly as they made it. It was always advisable not to be too sanguine; but the Directors honestly believed that they were not too sanguine with respect to the new process to which he had referred. After careful consideration, the Directors came to the conclusion that as they had made losses equivalent to the amount they proposed to write off, it was better to reduce the capital to the extent mentioned. He then put the resolution, which was carried unanimously.

The retiring Directors, Lieut.-Gen. Sir Andrew Clarke, R.E., G.C.M.G., and Mr. John S. Parkin, were then re-elected, as were also the auditors, Messrs. Broads, Paterson and Co.

An extraordinary general meeting was held subsequently, when

The CHAIRMAN proposed a resolution for reducing the capital from £400,000 to £80,000, divided into £60,000 "A" shares and 20,000 "B" shares, such reduction to be effected "by cancelling capital which has been called up but is unrepresented by available assets to the extent of £4 per share upon the 80,000 shares which have been issued and are outstanding, and by reducing the nominal amount of all the shares in the Company's capital from £5 each to £1 each."

The motion was seconded, and was carried with one dissentient, an amendment to the effect that the reduction in the nominal value of the share should be to £2 instead of to £1 not being seconded, and, therefore, falling through.

A vote of thanks to the Chairman and Directors was then proposed and carried unanimously.

Monte Video Telephone Company (Limited)

The annual ordinary general meeting of this Company was held at the offices, Gresham House, Old Broad-street, on Tuesday, Mr. Herbert Ward presiding.

The SECRETARY (Mr. E. M. Reiss) read the notice calling the meeting.

The CHAIRMAN, in moving the adoption of the report and accounts, said: Gentlemen, I will first call your attention to the statements contained in the two first paragraphs of the report. You will observe that during the year ended July 31st last our net profits amount to the sum of £6,895. 17s. 6d., which is about £500 more than the net profits of last year, and it must be remembered at the same time that last year's profits showed an increase of £1,622 over the previous year, so that there is no doubt that the Company's operations in Monte Video continue to make satisfactory progress, notwithstanding the prevailing hard times in Uruguay. The strictest economy has been observed in all matters relating to the general working of the Company, and all the *employés* have been called upon to bear reductions in their salaries, which I must add they have all done most cheerfully. The central office building in Monte Video has now become the unencumbered property of the Company, the last instalment of the purchase having been paid on March 6th last, since which time we have received regular monthly drafts from the manager. One of your Directors has only just returned from Monte Video, and I am happy to be able to inform you that he is thoroughly satisfied with the manner in which our business is conducted by the manager and his staff, and also with the condition of the Company's property; thus you will observe that the most recent report coincides with and corroborates statements referring to the same subject contained in my own report of last year after my visit to Monte Video. The number of paying subscribers is now 1,383, showing an increase for the year of 53, and with a return to more normal conditions in commercial circles generally in Uruguay there is no doubt the number would be substantially increased. The Directors have to announce that the Committee of the London Stock Exchange granted on June 12th last an official quotation to the Company's shares, both Preference and Ordinary. I now beg to move that the report and accounts be received and adopted, and shall be pleased to answer any questions or give any further information that proprietors may desire.

Mr. C. H. SANFORD seconded the resolution.

Mr. LOCK said that he would like to revert for one moment to the subject which he had the pleasure of discussing with the Chairman and Mr. Sanford that morning, and that was with regard to the way in which it was proposed to deal with the net profit for the year. It would no doubt be remembered by the shareholders that last year a considerable sum was made in net profit, and the whole of it was retained by the Board for the purpose of paying off part of the purchase price of the premises acquired in Monte Video, an object most desirable, but one which ought to have been dealt with strictly in the interests of the Preference shareholders. On the present occasion the same course was proposed, and the money which had been earned had been intercepted, as it were, by the Board, who, instead of paying the dividend to the Preference shareholders, proposed to take the money and use it for capital expenditure. Last year it was admitted by the Board at the general meeting that the net profit shown in the account was the property of the Preference shareholders, and it was a mistaken idea that the Board had the power to use that money as capital expenditure; and, therefore, instead of adopting the report, the Directors consented to modify their views on the subject, and they themselves proposed a dividend of, he thought, 3 per cent. per annum. On the present occasion he did not see how the Directors could do anything but adopt the same course, as the money belonged as much to the Preference shareholders this year as it did last year, and that being so it was difficult to understand how it was that the Directors had come to the conclusion to utilise the balance of net revenue for the purpose of paying the sum of money due for the Monte Video premises. On those grounds he asked the Directors to again modify their views, and propose a small dividend payable to the Preference shareholders as they did on the last occasion. He did not think that the Preference shareholders were at all anxious for the money itself, it would be quite sufficient for them to know that their rights were acknowledged. He proposed that a dividend of 4 per cent. or 5 per cent. should be declared, and as to the means of paying it he felt sure that the Preference shareholders would be only too glad to accept debentures or some such similar security.

Mr. PRAED said that he thought the Directors ought to take steps to prevent the spending of more money in Monte Video, which clearly should be paid in dividends to the Preference shareholders.

Mr. BALFOUR said that he must take entirely a different view of the subject. The Company was not in a position to raise further capital, and so he considered that the Directors were clearly justified in using the money in the manner they had. He thought that it was the duty of the Directors to get rid of, and not increase the paper money of the Company, and it was certainly the wisest and strongest policy to start in the future with a clean balance-sheet.

Mr. C. H. SANFORD (a Director) said that Mr. Lock asked the Board to recommend a dividend of 4 per cent. or 5 per cent., which was more than they had earned, without putting aside anything for depreciation. Such a course would be most absurd and disastrous, and he did not wish, as a Director of the Company, to do anything that would not bear the strictest investigation. They had taken since they first acquired the business £19,000 from the shareholders for the purpose of improving the property, and they had only failed to pay the dividend on the Preference shares because they had been obliged to pay for the purchase of the central premises. Of that sum, £2,737 might be said to have been contributed by the Preference shareholders in the last two years, and the rest by the Ordinary, and he considered that all the Preference shareholders should support the Board, and help to maintain the value of the shares and the reputation of the Company. The Directors had, in the bad times through which the Company had passed, managed by the strictest economy to show a better result than had been laid before the proprietors in good times.

Mr. LOCK said that he thought the only shares which had benefited had been the Ordinary.

Mr. C. H. SANFORD said that was not so. He had taken legal advice from his own solicitor on the matter of the dividend, and he had been told that in order to declare a dividend they would have to adjust the accounts and return to the Ordinary shareholders what had been taken from them. In answer to a question as to whether the Board expected any further heavy expenditure under the head of construction, he said that it was quite impossible for him to answer such a question definitely, but he could go so far as to say that the Board did not expect anything of the kind.

Mr. TOUCH said that he did not quite understand the question which had been raised with regard to adjusting the accounts. He thought that if the accounts had been passed in previous years, and a dividend had been paid, and if there was now a balance in favour of the Company, the Preference shareholders were entitled to receive that balance in dividends.

Mr. C. H. SANFORD said he had been legally advised that the adjustment must take place, and that the Company should raise money by debentures, if necessary all the shareholders contributing, and so make up the money they had expended on capital account. He had been advised that the Board had no power to declare a dividend in paper, as had been proposed.

Mr. TOUCH said that the difficulty with regard to the dividend arose from the fact that the shares were not cumulative. The Company had made the necessary profit to declare a dividend, and he thought it ought to be done; but the Preference shareholders could agree, instead of taking the money which the Company was in so great a need of, to accept promissory notes as they did last year, or the Board could give them debentures. It was only fair, he thought, that as the shares were not cumulative, the profits should be secured to them in some such manner.

Mr. C. H. SANFORD said he had been blamed for what had taken place last year, by one of the Preference shareholders. The Board could not declare a dividend and say that it was to be paid in paper as they had been advised to the contrary.

In reply to a question, the CHAIRMAN stated that they had no fear of the opposition Company in Monte Video.

Digitized by Google

After some further discussion, Mr. TOUCH moved the following amendment :—

"*Resolved, that the report and accounts be referred back to the Directors, in order that they may recommend the payment of a dividend of 3 per cent. per annum to the holders of the non-cumulative Preference shares of the Company.*"

And also the following resolution :—

"*That the Preference shareholders agree to lend the amount of the above dividend to the Company until such time as the Company is in a position to repay the same interest running thereon at the rate of 4 per cent. per annum until repaid.*"

Mr. ELLIAS seconded the motions.

Mr. JONES said that if the resolution were passed it could do no good.

In answer to Mr. Praed, Mr. SANFORD said that the Board did not anticipate they would have to take the revenue of the Company in the future for the improvement of the property, and the shareholders might rest content that such a thing would not be done if the Board could possibly avoid it.

Mr. PRAED suggested that the amendment should not be pressed.

The amendment was put to the meeting and lost.

Mr. TOUCH demanded a poll, and a difficulty arising as to the three shareholders necessary to make such a demand, the CHAIRMAN said that in order to take a poll as it was the desire of Mr. Touch, Mr. Sanford (one of the Directors) would make a legal demand for one.

Mr. SANFORD moved the re-election as a Director of Mr. E. F. Powers, which was seconded by Mr. JONES, and carried unanimously.

Mr. BALFOUR proposed Mr. Frank William Jones as a Director, and Mr. SANFORD seconded.

Mr. TOUCH moved that the question of electing a new Director be deferred for the present.

The election of Mr. Jones was ultimately agreed to.

Messrs. Gérard Van de Linde and Son were re-elected auditors of the Company.

Subsequently the CHAIRMAN declared the following result of the poll :—For Mr. Touch's amendment, none ; against, 21,785. For the Chairman's original resolution, 16,785 ; against, none. The amendment was therefore lost, and the original resolution carried.

A vote of thanks to the Chairman closed the proceedings.

International Okonite Company (Limited).

An extraordinary general meeting of the International Okonite Company (Limited) was held at Cannon-street Hotel, on Friday, October 27th, (1) to consider and, if thought fit, to pass a resolution to the effect "That the name of the Company be changed to 'The Okonite Company (Limited).'" (2) To consider and, if thought fit, approve the draft alterations in the Articles of Association of the Company submitted to the meeting. These resolutions to be submitted for confirmation as special resolutions to a second extraordinary meeting to be subsequently convened. Mr. Samuel Pope, Q.C., presided.

Mr. A. B. SEYMOUR (the Secretary) read the notice calling the meeting, and the proposed alterations in the Articles of Association were circulated amongst the shareholders.

The CHAIRMAN said that the meeting was of a special nature to consider resolutions for which the shareholders had already had notice. He would explain the position to them as clearly as possible, and detail the circumstances that had led to the calling of that meeting and the prospects of the Company. He could not allow any wide and general discussion however to take place. The history of that meeting was simply this :—It was a meeting called by the Directors in compliance with the wishes of a large section of the share and debenture-holders in the Company, representing about half the capital. It would be recollected that at the last meeting reference was made to the hopes that the Directors indulged in of success at Manchester. The position of matters on the other side of the Atlantic was that the Company was doing very good business indeed in New York, and making a satisfactory profit upon its operations, but at Manchester they had unfortunately been making losses, and the profits made in America had to go against the losses on this side of the water. The American board felt that this state of things could not continue, and they, therefore, sent a deputation from their body over to England, in order to see what steps should be taken to put an end to such an unsatisfactory condition of things. They arrived at the conclusion that the best course to pursue was to at once close operations in this country, and to really confine the business of the Company to America, where a profit was being made. Accordingly, in April last it was decided that the best course to pursue in the interests of the shareholders was to close the Manchester works, and as far as possible to get rid of all liabilities upon this side. The Board decided, however, to retain office until they met the shareholders and laid the position of affairs before them. They determined, however, not to take fees for doing practically nothing, although they had the right to draw fees and to remain in office till the year 1895. They felt that "it would be monstrous to draw their fees out of the Company practically for doing little or nothing." Their object was to make the Company successful. They had, within the last few days, received an encouraging statement from the other side in regard to the American business, and an independent investigation had been made at the instance of one of the members of the Board, and he stated that the result of that was that he was informed that the Okonite Company was one of the few commercial concerns in America that in the recent times of depression had made a satisfactory profit. The latest advices led them to believe that for 1893 the debenture interest would be paid, the Preference dividend, and a surplus left for the Ordinary shares. Therefore the present proposals were greatly to the benefit of the Ordinary shareholders, because there was no losing English business left to deplete the American profits, and since the Preference dividend was provided for already, all the surplus went to the advantage of the Ordinary shareholder. If times improved later on, and it was deemed advisable to do so, they might resuscitate the English business. If the resolutions were carried that day the Board in England would cease. He concluded by calling upon Mr. Short, one of the American Directors, to address the meeting, and afford any further particulars, and moved the approval of the resolutions.

Mr. SHORT seconded the motion, and said that it had been forced upon the American Board, and that there was no alternative but to take the course that they had done. It did not seem to American ideas to be the correct thing that they should be making profits there, and continuing a business in England which not only made no profits but involved a considerable loss. The position of the Company was such that they were unable to take advantage of market fluctuation in rubber, and they must have sufficient funds to enable them to do so, and to be independent of the banks. They were getting considerable orders in America, and he advocated the carrying of these amendments as essential to the well-being and future prosperity of the Company.

The CHAIRMAN said that the matter was now open for discussion.

A SHAREHOLDER : Have you sold the factory at Manchester ?

The CHAIRMAN : No.

ANOTHER SHAREHOLDER : Can Mr. Short tells us as to the likelihood of any dividend ; then we shall be on surer ground. I do not want a pledge.

Mr. SHORT : In regard to this it is very difficult to answer, and it is hardly worth while making a statement unless it can be made with some assurance ; but I can say this, that sooner or later we shall pay a dividend.

Mr. DOBREE, a Director, thought that was not a very hopeful way to put it.

Mr. SHORT said he meant that they would pay within a year or so, and in reply to another remark he said he thought they would pay the Preference dividend within a year.

The CHAIRMAN : Within this year ?

Mr. SHORT : Within the coming year.

The CHAIRMAN said that the latest statement from the other side to which he had already referred encouraged the belief that the result of 1893 would be to pay interest on debentures, dividend on Preference shares, and leave a surplus for ordinary dividend.

Mr. J. PUCKERIDGE asked the nature of the assets at Manchester, and if readily realisable.

The CHAIRMAN said that they consisted of freehold and leasehold premises, plant, and machinery. It was difficult to say what could be realised in the present depressed times, for instance, he should not regard a mill as readily realisable. Leakage had been stopped at Manchester. The liabilities were practically nil.

Mr. HOPPS said that he too had had an independent opinion from the other side as to the Company, which was of a most unsatisfactory nature, and he spoke of the manner in which it was regarded in Wall-street.

A disjointed discussion followed, in the course of which the CHAIRMAN said that they were not there to consider the question of what the Board did in getting rid of Messrs. Shaw and Connolly at Manchester. The success that they expected did not follow the steps taken, and this was due to the financial troubles in America. The question before the meeting was to amend the Articles of Association.

Mr. BOND wished to know if there had been an established loss of capital, and if it would affect the dividend when earned ?

The CHAIRMAN said it would not affect the dividend.

Mr. BOND said there were learned opinions to the contrary.

Mr. SHAW then proceeded to discuss the first alteration, viz., to rescind Article 35 and substitute the following :—"The Directors may accept surrenders of shares on such terms as they think fit," without any proviso. It was his desire that that Article should contain a proviso preventing the Company from investing money in its own shares or lending money upon the security of its own shares.

Mr. FREDK. RAWSON said that it seemed this resolution put the Company entirely into the hands of the American Board. He asked how many American Directors there were ?

Mr. VAUGHAN STEVENS (the Managing Director) said four.

The CHAIRMAN, in reply to a question, said that the Directors had not asked for proxies.

Mr. RAWSON asked if the American representative had a proxy from the American Directors, and how it would be used ?

Mr. CLEMENTS, the American representative, said that he had proxies for 5,366 Ordinary, 10,891 Preference shares, and the instructions from his principals were to vote for the amendments given notice of by the Board without amendment or modification, and he should do so.

Mr. RAWSON : That settles it then. We are in the hands of the Americans.

The CHAIRMAN said that the election of two new Directors, provided for by the new Articles, after the retirement of the present Board, was a matter for a future meeting.

Mr. RAWSON said that he had confidence in Mr. Short, the American Director. He (the speaker) had £8,000 in the Company, and he thought the shareholders in England ought to back up the English Board in refusing to do anything unless their views in this matter were accepted.

Mr. SHAW said he had given notice of six amendments, and he meant to read them.

Mr. HOPPS seconded Mr. Shaw's amendment.

Mr. BOND assumed that the American votes could carry the amendments by more than a bare majority.

The CHAIRMAN : More than half the capital.

Mr. BOND asked the effect of altering Article 35 in regard to the Stock Exchange quotation.

Digitized by Google

The CHAIRMAN said that he believed, if the Stock Exchange Committee choose to act upon it, that alteration of Article 35 would deprive the Company of their Stock Exchange quotation. He (the speaker) thought it a wrong amendment, and the English Board had urged the American Directors not to persevere in it, but they had been determined. He would be glad if Mr. Clements could be induced not to use his votes for that amendment.

Mr. CLEMENTS said that his instructions were positive, and he had no option in the matter.

The CHAIRMAN said it was practically impossible to unite against the block of nearly half the capital represented by the American Board.

Mr. RAWSON asked if a three-fourths majority was necessary.

The CHAIRMAN: No.

A SHAREHOLDER said that he was speaking in regard to Section 51 of the Act. If he was right in the fact he was right in the law.

The CHAIRMAN then said they must have three-fourths of those present.

In reply to a question the CHAIRMAN said that if he demanded a poll it would have the effect of wasting the time and money of the Company. They could not win against the American Board. The object of the alteration of Section 35 was to facilitate, he suspected, the different methods of American finance.

A SHAREHOLDER said it would prevent the sale of shares here.

The CHAIRMAN: There is no market.

Mr. RAWSON urged for an adjournment of the meeting, or a poll of the shareholders.

The CHAIRMAN: If you can get five shareholders, representing a fifth of the capital, demanding a poll I am bound to accept it.

Major JONES said he agreed with Mr. Rawson, and he would throw his own large holding into the scale.

A SHAREHOLDER: Perhaps Mr. Short can explain why the Directors in America insist upon this, and whether they know the probable effect would be to deprive us of a Stock Exchange quotation in London?

Mr. SHORT reviewed his connection with the Company, and said that if there was any special and particular motive in the amendment of Article 35 it had not been made known to him. He approved of the general policy of the American Board.

Mr. RAWSON suggested an adjournment and the appointment of a committee of three shareholders to send a "whip" round to defeat the American Board.

The CHAIRMAN: Nothing could be worse policy than to act in a spirit of hostility to our American colleagues.

After some further discussion the CHAIRMAN appealed to Mr. Clements as to whether he was compelled by his instructions to carry the alteration in the Article now under review (No. 35).

Mr. CLEMENTS suggested that all the motions should be carried to-day, as his instructions were definite, and that before the confirmatory meeting he would refer to the Board on the other side the views of the shareholders, with his own opinion thereon. He invited Mr. Shaw to send in his objections in writing.

Mr. RAWSON said that he thought Mr. Clements was "drawing a red herring across the trail," as the second meeting only required a bare majority. Mr. Clements was acting for the American shareholders.

The CHAIRMAN said then he should put the resolution, prefacing it by the remark that the meeting had given expression of considerable sympathy to Mr. Shaw's amendment, and reserved its right to impede or destroy the position of affairs at the subsequent meeting.

The CHAIRMAN then put the alteration to Article 35 to the meeting, and declared it carried.

Mr. SHAW asked that his amendments might be read.

The CHAIRMAN remarked that they had omitted to pass the first resolution for the alteration of the name of the Company, leaving out the word "Interna'ional" from the title of the Company, the name remaining "The Okonite Company (Limited)."

Mr. CLEMENTS then proposed, and Mr. STEVENS seconded, the change in the name of the Company, which was carried.

Mr. CLEMENTS then moved the other alterations *en bloc*, and Mr. STEVENS seconded.

Mr. SHAW moved his amendments, which were then read by Mr. STEVENS.

The CHAIRMAN said he did not agree with all of them.

After some further discussion the other resolutions were put *seriatim* and carried.

On the motion of Mr. CLEMENTS, seconded by a SHAREHOLDER, a vote of thanks was accorded to the Chairman, and the proceedings (which lasted two hours) terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

CENTRAL AMERICAN PUBLIC WORKS COMPANY (LIMITED).—The objects of this Company, which was registered on October 26th, with a capital of £100,000, in £10 shares, include the following:—To purchase, acquire, or construct, or cause to be manufactured, wires and cables of all kinds for the purpose of telegraphs and telephones, to lay and work the same, and to carry on the business of telegraphy and the transmission of messages in all its branches and in all parts of the world.

PATENT PLATE STRUCTURE COMPANY (LIMITED).—This Company was registered on October 25th, with a capital of £10,000, in £5 shares, to carry on the business of mechanical engineers, iron and brass founders, machine and engineering tool makers, metal workers, boiler makers, &c.

LONDON AND HAMPSTEAD BATTERY COMPANY (LIMITED).—The first annual return of this Company, which has just been filed, shows that out of a nominal capital of £50,000, divided into 7,000 £6 per Cent. Cumulative Preference and 3,000 Deferred Shares of £5 each, 615 of the Preference and all of the Deferred Shares have been subscribed for and allotted. The whole of the Deferred Share capital has been issued as fully paid. Upon 249 of the Preference Shares the full amount has been called, and upon the remaining 366 shares a call of £3. 10s. has been made. The calls paid amount to £2,170, leaving the sum of £356 in arrears.

FORD-LLOYD MANUFACTURING COMPANY (LIMITED).—The statutory return of this Company, made up to October 18th, has been filed. The nominal capital is £10,000, in £1 shares, and 4,207 of these have been taken up, of which 4,000 were issued as fully paid to Edwin J. Tumber and Arthur Ford-Lloyd, in consideration for the sale to the Company of the business of electrical engineers carried on at 8, Mount-pleasant, Clerkenwell, E.C., including the sole rights of sale in connection with the E. S. Dry Battery. Upon the remaining 207 shares the full amount has been called and paid.

HALIFAX AND BERMUDAS CABLE COMPANY (LIMITED).—The usual annual return of this Company, made up to October 4th, shows that the whole nominal capital of £50,000, in shares of £5 each, has been issued as fully paid, the paid-up capital being nil.

CITY NOTES, &c.

ALUMINIUM COMPANY (LIMITED).—The report for the twelve months ended June 30th last states that the Oldbury trading account shows a profit of £7,245, but this amount was not quite sufficient to meet all fixed charges at the head office, including debenture interest. The volume of the Company's business has increased very rapidly during the last few months. The Directors think this a suitable time to re-arrange the capital, and at an extraordinary meeting a resolution will be proposed to write off £4 per share, thereby reducing the nominal value of £1 per share. The Directors believe that the present income of the Company will be sufficient to meet all fixed charges, to provide adequately for depreciation, and to leave a balance for dividend on the reduced share capital.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended October 29th were £848, as against £889 for the corresponding period of last year, being an decrease of £41. The total receipts for the half-year amount to £13,766, against £13,509 in the corresponding period of 1892, being an increase of £257.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the month of October, 1893, amounted to £61,409, and to £61,069 in the corresponding period of 1892.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the month of October, 1893, amounted to £41,443, and to £43,342 in the corresponding period of 1892.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The Directors have declared an interim dividend on the capital paid up on the Ordinary shares of the Company at the rate of 10 per cent. per annum for the six months ending November 30, 1893, the dividend to be payable on and after December 1st next.

GENERAL ELECTRIC COMPANY (OF AMERICA).—The Board of Directors have made an interesting announcement to the stockholders concerning the sale of the treasury securities, which it is declared have a nominal value of $12,000,000. These securities have been sold to a syndicate which has formed a company to be known as the Street Railway and Illuminating Properties, for an amount understood to be $4,000,000, and this money will be used to take up the Company's floating debt. 45,000 shares of Preferred stock of the new company and 45,000 shares of Common stock are to be issued against these $12,000,000 securities, which are bonds and stocks of local street railways and illuminating companies which the General Electric Company has received in payment for plants and for royalties. Many of the securities are paying dividends, and the syndicate estimates that these dividends will be equal to a 6 per cent. dividend on the $4,500,000 Preferred stock by the new Company, or $270,000, and "substantial sums on the Common stock." The shares of the Street Railway and Illuminating Properties are offered to the General Electric stockholders in blocks, each block to consist of one Preferred and one Common share. The price for each block will be $100, and all stockholders of record at the close of business, October 27th, holding eight shares, will be enabled to subscribe for one such block.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a special settling day and to grant a quotation to the Perpetual Four per Cent. Debenture Stock of the City and South London Railway Company.

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended October 27, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,704.

STOCK EXCHANGE.—Wednesday last being the 1st November, the London Stock Exchange was closed; hence the following prices of securities are made up to Tuesday evening, instead of Wednesday evening, as usual.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 808.—Vol. XXXII. FRIDAY, NOVEMBER 10, 1893. PRICE SIXPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

Now that the lamp monopoly is at an end, so far at all events as the master patent is concerned, many a box full of old lamps which had been put away will be opened. We must confess some surprise at the thoroughness with which the Edison and Swan United Company managed to keep the field to themselves. The suppression of large firms by accidents of the law and by lavish expenditure of the shareholders' money was comparatively simple, but the surreptitious use of contraband lamps was much smaller than might have been expected. The Company kept a sharp look out, but Woodhouse and Rawson lamps were not long ago still used in the Midlands, in perfect innocence, by those who had purchased them from dealers or agents, and in complete ignorance of any monopoly. The natural extinction of such lamps, and the stoppage of further supplies has left probably very few in regular use. One evasion of the monopoly was practised for a long time without hindrance, namely, the use of contraband lamps for temporary lighting for balls, &c. The excuse was that these lamps were never sold, they were used for a night and taken back again into stock. The Edison-Swan United Company have been much more successful in strangling illicit competition than the Telephone Company. Scores of imported or of home-made telephones were in use during the monopoly, and as a telephone has a longer life than a lamp, a considerable proportion no doubt still exist.

Anyone wishing to make a resistance for merely getting rid of a few watts, and not caring about its exact value in ohms, will find that a filament of carbon attached to platinum wires, and sealed into an exhausted glass globe, in many cases serves the purpose admirably. But for the last four or five years there has been some difficulty in buying such resistances, because, on passing a fairly large current, say one-third of an ampere, through them, they became so hot that they emitted light. This did not interfere with their usefulness as resistances, but to make or to use them was illegal. Nevertheless, such resistances have been bought and sold within the last few years; but, so far as we know, they were always used as resistances, and not as lamps. Restrictions are now largely removed, and it is worth noting that for getting rid of a small amount of electrical energy for laboratory work, a lamp is the cheapest kind of resistance that can be used. It may turn out that some of the new lamps will be fit for little else.

The report of the Committee of the American Street Railway Association on "Power House Engines," abstracts of which we publish this week, contains some recommendations which, while indicating a change in American opinion, is not quite in accordance with practice in our own country. For a very long time direct-coupled dynamos and steam engines have had the upper hand in the electric lighting stations here, and have been as completely ignored in America; while, on the other hand, we have furnished our large electric railway "power-houses," as the Americans call them, with rope or belt-driven dynamos. It is not a little curious, therefore, to find that direct-coupled dynamos are recommended for generating stations for electric railways by the Committee at Milwaukee. There appears to be a decided fitness in direct-coupled plant for electric-light stations, which is not yet applicable to the same kind of plant when placed in large railway power-houses. For, in the former, the character of the load diagram is such that there must be extensive sub-division and small units of power, and the change of total load is so gradual that a very considerable part of the plant may be shut down for long periods. But in the latter the character of the load diagram is altogether different, and is such that it is impossible to shut down any but the reserve plant, for the load varies so suddenly and so largely that the full capacity of plant must always be on the *qui vive*. In this latter case, therefore, extensive sub-division and small units of plant are inappropriate. Now, where the dynamo is of moderate power, it is very practicable to design a steam engine which will run coupled to it; but where the unit of power is very much larger, it is often found to be impracticable to adapt the steam engine to the high speed which the dynamo should have, and costly to adapt the dynamo to the low speed of the engine. The engine and dynamo suit themselves and one another better where they run at different speeds; hence the necessity for gearing, a confession of inability on the part of most engine builders to run their engines fast enough.

The continued high price and scarcity of coal must at length be telling seriously upon both the electric light and the gas industries. Some ignorant daily papers have been patronisingly telling us that now is the chance for electricity to take an advantage over coal gas—now, when the price of coal gas is bound to take an upward trend. But it is of course equally expensive to purchase coal for the one mode of lighting as for the other; while both have had an equally good chance of arranging for long-term contracts at fixed prices,

Digitized by Google

Electric supply stations are, as a rule, very badly off for coal storage compared with gas works. As a matter of fact, however, we know of one instance—and doubtless there are others—where the boilers at the electric-light station are supplied with coal from the gas works. This looks at first like brotherly love of a very millenium order; but is explained by the fact that both gas and electric-light works are owned by the same Corporation—the municipality. Anyway, money is being made and lost somewhere by the high prices in coal; and if the contract prices are favourable to gas and electricity production at the present time, it is a safe prediction that the next renewal of contracts will find the case quite altered. On the other hand, those generating stations which are not sheltered by favourable contracts must be thinking it is about time to raise the price of their units or their 1,000 cubic feet, as the case may be.

A SUB-COMMITTEE of the proposed Universal Exhibition at Paris in 1900 has decided on the Champ de Mars as a site, thus utilising the Eiffel Tower. It appears that at present it is not intended even to compete with the follies of Chicago. It is possible that by the time 1900 comes round nobody but strike agitators and colliers will have any money to spend on such amusements.

THERE is a time to speak and a time to be silent. So long as HARNESS continued to advertise profusely, the daily press stood by him and helped to spread lies. But no sooner was he arrested on a charge of conspiring to commit fraud than they all throw him over. The London evening papers flaunted the news on their posters, dropping the "Mr." in the later editions. They might have had the decency to draw a veil over the misfortunes of one who had been so good a friend to them in the days of his prosperity. This would have been a time for graceful silence on their part.

New Atlantic Cable.—It has been decided by the Commercial Cable Company to lay another cable next year.

Cable Interruption:

	Date of Interruption.
Paramaribo-Cayenne	October 25, 1893.

Tasmania.—An International Exhibition of Industry, Science, and Art will be opened at Hobart Town, Tasmania, in November, 1894, and will remain open during about six months.

Southampton Docks.—Recent further official trials of the electric crane which has been erected on the Town Quay have proved to be satisfactory, and a second electric crane is in process of erection.

Windsor.—New wires have been laid between the Queen's private telegraph office at Windsor Castle and the Borough Post Office at the corner of High-street and St. Albans-street, in readiness for Her Majesty's use upon the return of the Court from Balmoral this month.

The "Harness" Case.—An order of the Chancery Division of the High Court of Justice was made last Saturday by Mr. Justice North, directing common accounts and inquiries in *re* Wilkinson *v.* the Medical Battery Company, with liberty to apply for the sale of the business as a going concern. Further reference to the Company will be found on page 51.

Breakdown on the St. Pancras Lighting Circuit.—At about 7:30 last Tuesday evening the neighbourhood of Gloucester Gate, Regent's Park, was suddenly thrown into a state of perfect darkness owing to the failure of the electric light, which by some means became extinguished. The current was not restored till nearly an hour had elapsed.

Science at Oxford.—At a recent debate in the Oxford Union Society the claims of science upon the University were considered. Mr. J. L. S. Hatton, M.A., urged that "the greatest study of the age was science, and its greatest branches engineering and electricity." Finally, he warned the University of the possible consequences of not extending their science teaching, when it was increasing at such a rate throughout the land.

Electric Lighting of Winchester.—The premium offered by the Corporation of the City of Winchester for the best scheme submitted for the electric lighting of the city has, on the report of their consulting engineer, Mr. Morgan Williams, been awarded to the Brush Company. The city is at present lighted by oil lamps, and has been discussing the adoption of electric lighting in a desultory way for about ten years.

Copenhagen.—The sale of electric current from the Copenhagen central station, through meters, amounted during the last six months of 1892 to 163,907,300 watt-hours, and during the first six months of the present year to 144,828,600 watt-hours. On January 1, 1893, there were about 14,800 lamps of 16 c.p., which number during the first half of the present year had risen to about 16,000 lamps. The consumption during the first half of 1893 was not so large as calculated.

Electricians and the Royal Humane Society.—At a recent meeting of the Royal Humane Society it was unanimously resolved to confer the Society's honorary testimonial on each of the following members of the crew of the steamship "Silvertown":—Sub-Lieutenant F. W. Robinson (R.N.R.), Messrs. Hugh Livingstone, H. Grimes, J. Miller, and A. Day, junior, for their courage and humanity in having saved the life of W. Bobbitt, a cable hand, who was in imminent danger of drowning by the upsetting of a surf-boat in the surf at Salina Cruz, on the Mexican coast, when two lives were unfortunately lost.

Electric Fighting Men.—It is said that a Mr. Doric Cheater (save the mark) has offered to the Spanish Government, for the trifling sum of five million pesetas, his invention of "an automaton soldier made of forged iron, capable of firing 40 shots a minute at the enemy," the machine being manipulated electrically. In the place where a soldier's brains ought to be the automaton is stuffed with dynamite; so that his captors would get a severe "blowing up" in the event of his being taken prisoner. It is not said what would happen if *both* armies were composed of electric automata!

Lightning Express Railway Service System.—We are informed that Mr. F. B. Behr has made arrangements with the Thames Ironworks and Shipbuilding Company for carrying out experiments on a large scale on this system, with a view to perfecting the electrical details. This system, which is commented on in *The Electrician*, Vol. XXXI., p. 526, is based on the Lartigue single rail system, and has been worked out very thoroughly by Mr. Behr. It is to be hoped that the great difficulties which necessarily beset an express railway service will be found to be not insuperable, but that the efforts which Mr. Behr is making will be crowned with success.

The London County Council and Technical Education.—The Finance Committee recommended, and it was agreed, that the balance of the £30,000 which the Council on March 28th last appropriated for the purposes of technical or manual instruction, being part of the moneys received by the Council under the Local Taxation (Customs and Excise) Act, 1890, in respect of the financial year ended March 31, 1893, should, after deducting £677. 9s. 11d. for expenses and £2,000 which had been advanced on account to the Technical Education Board, be handed over to that Board, as they considered it desirable that the funds should be administered through and by it.

Society of Arts.—The first meeting of the 140th session of this Society will be held next Wednesday, November 15th, when the opening address will be delivered by Sir R. E. Webster, M.P., Chairman of Council. Among the Papers announced to be read after Christmas we notice the following "Automatic Balance of Reciprocating Machinery and the Prevention of Vibration," by W. W. Beaumont; "The St. Pancras Electric Light Installation," by Prof. Henry Robinson;

Digitized by Google

"Electric Signalling Without Wires," by W. H. Preece, F.R.S. A course of Cantor lectures on "Photometry" will be delivered on April 2nd, 9th, 16th by Capt. W. de W. Abney, F.R.S.

Racing Extraordinary!—A Paris Paper, says the *Indian Engineer*, reports that a company has been formed at Madison to construct a Hippodrome, the like of which has never been seen. It will consist of a long racecourse perfectly straight and of two stands each capable of seating 5,000 people which are to run on rails laid each side of the course. These stands are to start at the same time as the horses and will keep up alongside of them (being driven by steam or by electricity), and spectators will be able to watch every race from start to finish. Up to now jockeys are the only people exposed to any risks of accidents on the turf; now these risks will be shared by the public and bets can be made on the chances of a general smash-up.

Cambridge.—The Engineering Laboratory Syndicate ask for a grant of £1,000 to enable them to complete the buildings required for the accommodation of the department. From private sources nearly £5,000 have been subscribed for the purpose, but this is insufficient for the whole of the work in contemplation. Prof. Ewing reports that no less than seventy-four students have entered for courses in engineering during the present term; and it is very desirable that their work should not be hampered by delay in providing the necessary rooms for their accommodation. It had been hoped that subscriptions towards so valuable an extension of the scientific equipment of the University would flow in liberally, but the stream of benefaction seems for the present to have dried up.

Royal Society.—The following is a list of those who have been recommended by the President and Council of the Royal Society for election into the Council for the year 1894, at the anniversary meeting on November 30th:—President: Lord Kelvin. Treasurer: Sir John Evans. Secretaries: Prof. Michael Foster, Lord Rayleigh. Foreign Secretary: Sir Joseph Lister. Other members of the Council: Prof. Isaac B. Balfour, Andrew A. Common, Andrew R. Forsyth, Richard Tetley Glazebrook, Prof. Alexander H. Green, Sir John Kirk, Prof. Oliver J. Lodge, Sir John Lubbock, William D. Niven, William H. Perkin, the Marquis of Salisbury, Prof. J. S. Burdon Sanderson, Adam Sedgwick, Prof. Thomas E. Thorpe, Prof. William A. Tilden, and Prof. W. Cawthorne Unwin.

The Junior Engineering Society.—On the afternoon of Saturday, 21st ult., a large party of members of this Society visited the Tilbury Docks of the London and India Docks Joint Committee, and the p.s. "Royal Sovereign," of the Victoria Steamboat Association. They were shown over the docks by Mr. Seater, on behalf of the superintendent, Mr. R. Adams. The hydraulic power engine and boiler houses, electric light plant, hydraulic travelling cranes, sheds, the dry docks and their pumping machinery, lock, deposit removing apparatus, and other features of engineering interest were seen. The "Royal Sovereign" was viewed under most favourable conditions, the vessel being in dry dock at the time. Mr. Peter Blair Black, the Association's consulting engineer, and designer of the vessel, received the party, and showed them round.

Metropolitan Electric Supply Company.—The Metropolitan Electric Supply Company, in a circular just issued, state that the increase of business is being satisfactorily maintained. The number of lamps connected to the Company's system, which in November, 1892, amounted to 114,656, and at the date of the general meeting in April last to 134,453, now amounts to 1[illegible]7,556, and additional applications are in hand for the supply of current to 7,557 lamps. The gross revenue for the six months ended June 30, 1893, shows a very satisfactory advance upon that for the corresponding period of 1892, while the working expenses for the same period fully bear out the view which the Board have frequently expressed as to the small additional cost of production as compared with the increased revenue earned. The gross revenue for the quarter ended September 30th shows, it is stated, that the rate of increase over 1892 continues.

A Portable Electric Lamp.—At a recent meeting of the North of England Institute of Mining and Mechanical Engineers, Mr. V. C. Doubleday exhibited and described a new electric lamp, specially designed for the use of miners. The appliance, which bears the name of the Sussmann lamp, is about the size and weight of a miner's "Davy," which it resembles in shape. It gives light, however, from the top instead of from the bottom, and emits a fairly brilliant beam of about three candles. The source of energy is a secondary battery, which is charged from a dynamo in the ordinary way. The Sussmann storage cell, however, is stated to be absolutely dry. There is obviously some exaggeration here, but it is no doubt possible that liquid acid is dispensed with. Double protection is afforded to the carbon filament, which, besides being necessarily enclosed within a vacuum bulb, has in front of it a plate of thick glass. It yields its normal light for a period of 16 hours, but can be so constructed as to give a larger output for a shorter time.

An Electric Turntable.—An expert in railway matters declares, says the *Electrical Review* of New York, that the day is not far distant when the switching engine will be entirely done away with, its place being taken by the electric capstan. The latter is already in use to a certain extent on some of the Pennsylvania lines. The motor, which actuates the capstan by means of gearing, runs at the rate of some 1,200 revolutions a minute, and the gearing, motor and switch of the capstan are all contained in a water-tight iron case, the top of which comes flush with the ground; there is a cover to it which is readily removable, so as to give easy access to the motor for oiling and cleaning. The wires containing the current for the motor are carried through an iron pipe below the surface of the ground, and the switch for starting and stopping the motor is operated readily by the foot of the attendant in charge of the capstan. Such capstans were made in this country some years ago, but it is doubtful whether they are superior to hydraulic capstans in common use.

An Electric Railway Trial.—The managers of the Intramural Railway at Chicago have for some time felt, says the *Electrical World* of New York, that trains much heavier and longer than ordinary lines could be operated, and recently made a trial to prove that this was the fact. W. E. Baker, manager of the road, late at night started out a train composed of one live motor car, two still motor cars, and nine empty cars, weighing in all about 196 tons. This heavy train was pulled along apparently without effort, even when it turned the loops at either end of the road, each of which has a radius of over 100ft. On the following day, which was "railroad day," invitations were issued to the railroad magnates assembled at the Exposition, and a train of eight cars (one motor car and seven trailers) was provided. The train was loaded to its fullest capacity, no less than 800 persons being carried. The motors ran smoothly at their maximum speed, and the test was satisfactory in every respect. The weight of the train can be estimated at 212½ tons. This performance may be compared favourably with that on any steam elevated railroad, and speaks well of the confidence of the managers in their road and its equipment.

Electrical Communication with Lightships.—Two new vessels are being prepared under the direction of the Trinity House to relieve the lightships at the North Goodwin Sands and the Kentish Knock. The new ships are being built under contract, and they embody many improvements upon the lightships of older type, each being supplied with powerful syrens, the one for the North Goodwins being worked by steam, and that for the Kentish Knock by a hot-air engine. Both vessels will be in direct electrical communication with the shore, the cable from the North Sands having its land connection at Dumpton Gap, and that from the Kentish Knock at Kingsgate Bay. The Post Office authorities, as we have already announced, will lay the cables, and the cost of the work and maintenance charges will be defrayed out of moneys specially voted for the purpose by Parliament. For nearly 20 years the Goodwins have been protected by four lightships in addition to intermediate buoys. The vessel at the North Sand Head is the oldest, having been established exactly 100 years; the Gull lightship took up its position in 1809; the lightship at the South Sand Head was moored there in 1832, and the one on the easterly side of the bank in 1874, the number of wrecks diminishing as each additional light was brought into use.

The Care of Boilers.—Boilers when not in use require as much care as when under steam; yet frequently they receive less. The French naval authorities have recently issued an important order on this subject, which is well worth noting:—

"On board all ships in the reserve, as well as on those which are laid up, the boilers will be completely filled with *fresh* water; and this is to apply to shell boilers as well as to those of the tubulous or pipe type. In the case of large boilers with large tubes, there will be added to the water a certain amount of milk of lime, following the instructions furnished by Belleville and Co. for the preservation of the tubes of their boilers, or a solution of soda may be used instead. In the case of tubulous boilers with small tubes, milk of lime or soda will be added (but the solution will not be so strong as in the case of the larger tubes), so as to avoid any danger of contracting the effective area by deposit from the solution. The strength of the solution will just be sufficient to neutralise any acidity of the water. Care must also be taken to preserve the outside of the steel or iron tubes in the case of boilers which are not to be used for long periods. To this end they will be painted with red lead or coal tar as far as it is possible to reach. For those places which are inaccessible, a protective coating will be obtained by burning under the tubes a certain amount of tar or coal tar, whose smoke will form a coating of soot, and thus prevent the air from reaching the surface of the tubes. In addition, the boiler casing will be closed and kept air-tight after placing inside some quicklime. Periodical inspections of boilers thus treated will be made, to ensure the complete filling of the tubes with water."

The Institution of Civil Engineers.—The seventy-fifth session of the Institution of Civil Engineers will be commenced on the 14th inst., and the meetings before Christmas are likely to be occupied—in addition to an address from Mr. Giles, the President—with the design and construction of impounding reservoirs for water works at Tansa (Bombay), Baroda, and Jeypore, with machinery for the manufacture of casks, and with the development of hydraulic power supply in London. Among the subjects on which Papers are invited are the following:—The cost of working electrical tramways, taking account of interest on capital, and of a sinking fund for depreciation; the most suitable form of electric light mains, having regard to durability, economy of conducting material and facility for making and laying house connections; the risks of electric lighting to life and property, with the means to be taken to prevent or to reduce them; the best arrangement of engine for any given electric light station; electrical motors for (*a*) inland navigation, (*b*) ocean vessels; electric lighting and haulage plant in mines and collieries; the effect of small quantities of impurities in commercial copper as regards its use in electrical work; the electro-deposition of copper; on the application of water power and its transmission to a distance by electricity; the design of electric locomotives; the practical working of multiphase alternate-current motors; the forms of electrical conductors for lighting, stationary power, heating and traction purposes.

Patent Law in the United States.—In the recent Western Electric (Scribner) arc lamp decision, says the *Electrical World* of New York, two important points of general interest are defined by the United States Court of Appeals, before which the case came. The first relates to the distinction between the abandonment of an invention and the abandonment of an application for letters patent by failure to carry out certain provisions of law. The Court held that besides the power conferred upon the Commissioner of Patents to relieve an applicant from an abandonment of his application under the statute, an application which had lapsed or been rejected or withdrawn may be renewed or repeated so long as the invention itself has not been abandoned by reason of a two years' public use, or otherwise. The other point has a collateral bearing on the trolly cases now in Court, as it relates to the question if the change in functions of a device constitutes an invention. The Court holds that the invention is in the device. In the case at issue the judge illustrated the distinction by the statement that the "magnetic current" (*sic*) itself is not a part of the device any more than water is an element of a water wheel; in one case water is the power and in the other the electric current, and devices are contrived for the purpose of controlling and applying the power. This view is interesting in connection with the claim that the fundamental mechanical principles involved in the street railway trolly were anticipated by numerous patents previously issued for trollies to be used in the operation of telegraph instruments on steam railway cars, and therefore the trolly patents in litigation are void through resting on a mere functional difference—conveying a small current to a telegraph instrument in one case and a large current to a motor in the other.

A 1,000 H.P. Electric Locomotive.—This locomotive, says the *Electrical Engineer* of New York, is the outcome of the resolve made some two years ago by the President of the North American Company, after consultation with Mr. F. J. Sprague, to ascertain to what extent electricity could be applied to the railways under his direction. A board of engineers appointed by him drew up a set of specifications embodying their recommendations, but these have been radically departed from in the actual locomotive. This locomotive, which is nearing completion, has been constructed to test the feasibility of handling freight at the terminal yards of the Chicago and Northern Pacific and Chicago North-Western system at Chicago. The problem included the design of an electric locomotive of ample power, which could be controlled as readily and be as reliable as a steam locomotive. Secondly, it involved a set of conductors and method of supporting them which could be relied upon for ample supply of current and continuous contact at all speeds on curves, switches, and cross-overs; and, finally, an automatic block signalling system which would not be thrown out of operation by the use of the tracks as conductors. Of the seven or eight designs prepared, the one adopted sticks closely to the best established steam locomotive practice: a rigid frame and a multiplicity of drivers connected together; and to these are added armatures mounted directly on the axles, and field magnets rigidly carried on pedestal boxes, the equalising spring movement only affecting the superstructure. This construction is in marked contrast to the methods more recently advocated, of suspending the armatures on sleeves concentric with the axles; but the reasons which have led the designers to the form adopted would appear to be thoroughly well based on past experience.

The Comparison of Specific Inductive Capacities.—To those interested in the determination of comparative specific inductive capacities, says a writer in the *Electrical World* of New York, one of the greatest drawbacks to experiment in this direction is the necessity for the employment of great condenser surface in order to obtain, by the usual direct deflection method, readings sufficiently great to be reliable. The writer having had occasion to compare the specific capacities of a number of insulating substances, and having been met on the threshold of his investigations by the obstacles referred to, devised a simple method, by the use of which it was possible to obtain satisfactory results, even when exceedingly small surfaces were used. The apparatus required is an electrically-vibrated tuning fork, of about 280 double vibrations per second, one limb of which is provided with a platinised extension vibrating between two light platinised springs, which are limited and damped so that their individual periodicities may not conflict with that of the fork. These springs are adjusted relative to the fork extension, so that when in vibration it shall make contact with them alternately, but shall be out of contact with both springs at the position of rest. The tuning-fork is well insulated, and provided with a binding post for the attachment of the lead. One spring is connected with the pole of the battery, the other spring to one terminal of galvanometer, and the fork to one terminal of condenser, the other terminals of the battery, galvanometer, and condenser being connected together. The action when the fork is in vibration is that at one limit of swing the condenser is charged by contact with the battery spring, and at the opposite limit the charge is neutralised through the galvanometer by contact with the other spring. The succession of impulses being so rapid (280 per second) the effect upon the galvanometer is nearly that of a continuous current, and the deflection consequently steady. The rate of vibration of 280 was adopted because it nearly approached the rate of the vibrational induced currents on telephone lines, due to electric light circuits; any other rate might be adopted but the higher the more difficult of adjustment, and the lower the further removed from continuity are the discharges. It is possible with this arrangement to measure the static capacity of a person insulated from the floor, and to note the increase of capacity due to the approach of other (uninsulated) persons to him, when using a Thomson reflecting galvanometer and fifty cells of battery.

THE PRINCIPLES OF THE CALCULUS.

Engineers are often afraid of the differential and integral calculus, because they think it is difficult and savours of too much "theory." Yet it is wonderful how often the principles of the calculus enter into the thoughts of practical men. There are two distinct ideas in the calculus: the idea of a "rate" and the idea of a "summing up," or the differential and integral ideas as they are called. The idea of a "rate" or "rate of change" enters into many engineering questions. The horse-power of a motor is its rate of doing work, and the velocity of a body is its rate of change of place. There are two ideas involved when we set a motor to do a piece of work: the idea of the total work to be done, and the idea of the time in which the work is to be done. If the motor works always at the same rate, its power at any time is equal to the total work done divided by the time. But very often the motor works at a very irregular rate, so that its power at any instant cannot be so determined. In this case we may suppose the motor to work for a fraction of the time at one rate, then for a fraction of the time at another rate, and so on. The motor will do the work irregularly, but the work which it will do during each fraction of the time that the rate is constant will be equal to the product of that rate into the fraction of time; or the rate during this time will be equal to the portion of work done divided by the time. Now, if the motor changes its rate of working very frequently it will not be able to do much work in each little bit of time that it is working at a constant rate. Still, the rate will always be equal to the ratio of the little bit of work done to the short bit of time it takes to do it uniformly. But if the motor is constantly changing its rate of working, so that at each little interval of time it is working at a different rate to the interval before and after it, we cannot consider that there is any length of time, however short, in which it is working at a perfectly constant rate. If we consider a large fraction of the time we find that the rate changes very much in that time, and is very different at the end to what it was at the beginning. If we consider a shorter length of time we find that the rate has not changed quite so much. And the shorter and shorter we consider the little bit of time, and the work done in that time, the less and less shall we find that the rate has changed; although we shall also find that the little bit of work done has diminished, too, as the time is shorter. Now, if we take a very, very short bit of time, so infinitesimal in its duration that only an infinitesimal bit of the work will be done in it, we shall of course find that the change of the rate of working in this time will be infinitesimal, or, in other words, that the rate is constant within measurable amounts. And if the rate is constant during this brief time it is, as we have already seen, measured by the ratio of the bit of work done to the brief time occupied in doing it. But both of these are infinitesimally small. We call the infinitesimal bit of work *the differential of the work*, and the infinitesimal bit of time *the differential of the time*; so that

$$\text{Power} = \text{rate of working} = \frac{\text{differential of work}}{\text{differential of time}}.$$

If we call the power P, and the differential of the work $d\,W$, and the differential of the time, $d\,t$, we have the expression

$$P = \frac{d\,W}{d\,t}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and this form of expression is called a *differential coefficient*, or the differential coefficient of W with respect to t. If, instead of P, W, and t, we have any three variable quantities which depend on one another in some way, such as z, y, and x, we put

$$z = \frac{d\,y}{d\,x}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

z is the differential coefficient of y with respect to x. This means simply that the value of z, which is obtained by dividing the little bit of y, $d\,y$ by the little bit of x, $d\,x$, which corresponds to it, gives us the exact *rate* of change of y with respect to x; so that the idea of the differential calculus is contained in a nutshell in the easily understood idea of a *rate*.

Not more difficult is the idea of the integral calculus, which is the notion of "summing or adding." Let us return to our consideration of a motor which is doing a piece of work, W, at a varying rate. The whole time, t, in which this work is done is composed of a succession of little bits of time, $d\,t$, following one another in a sort of stream, and there is a different value of P in each separate differential of the time. If we transpose the equation (1) for P, we can get

$$d\,W = P\,.\,d\,t.$$

That is to say, the little bit of work done in the time $d\,t$ is the product of P, the power, into $d\,t$. Let us number the successive differentials of time $d\,t_1$, $d\,t_2$, $d\,t_3$, and so on, and the power in each P_1, P_2, P_3, and so on. Then the little bit of work done in the first is

$$d\,W_1 = P_1\,d\,t_1,$$

and in the second

$$d\,W_2 = P_2\,.\,d\,t_2,$$

and so on, but the whole work, W, done in the whole time t, is the sum of all the fragments of work done in the successive fragments of time, or

$$W = d\,W_1 + d\,W_2 + d\,W_3 + \quad . \quad . \quad . \quad . \quad .$$
$$= P_1\,d\,t_1 + P_2\,d\,t_2 + P_3\,d\,t_3 + \quad . \quad . \quad . \quad .$$

Now we cannot add these little elements (as they are called) by the rules of ordinary addition; firstly, because there is an infinite number of them; secondly, because they are all different in size; thirdly, because they are each so infinitesimal that we cannot attach any numerical value to any single one of them. And yet, if we could find some method of summing up all these elements of work, we should get the total work done. Such a method is found in the integral calculus, and is called *integration*. Thus, if we wish to express that the expression

$$d\,W = P\,.\,d\,t$$

is to be integrated, we write the sign of integration, $\int$, before it, thus:—

$$W = \int d\,W = \int P\,.\,d\,t$$

Or, W is the integral of $d\,W$ or the time integral of the power. In order actually to perform the operation of integration we must, of course, know something of the law by which P, W, and t vary among themselves.

THE UNITS OF HEAT AND TEMPERATURE.

The C.G.S. system, as we have remarked some time ago, fails to directly include heat and temperature among the quantities which it defines. Some of the earlier attempts in this direction were merely due to a desire to gather all physical quantities under one uniform system. For all ordinary purposes the Centigrade scale is perfectly satisfactory. For extreme temperatures or for exceptional accuracy the necessary thermometer must be abandoned, and the scale of the air thermometer is used. In the researches of Profs. Dewar and Fleming the use of an air thermometer is, of course, out of the question, since air liquefies at the low temperatures employed. Extrapolation of the straight part of the scale might suffice, but either this or the hydrogen thermometer are only conventions. The recent results of Profs. Dewar and Fleming were expressed in "platinum degrees." This scale, though curved relatively to the air thermometer, at all events extends to the required range. The consideration of an absolute scale of temperature hence acquires a new interest.

Shortly after the last Electrical Congress at Paris some suggestions were made by Prof. Forbes and Mr. W. H. Preece with reference to the establishment of a true scale of temperature. Their views are stated by them in an article which appeared in *The Electrician* for September 20, 1889. The Units Committee at the Bath meeting of the British Association had suggested the *therm* as the unit of heat, while the French Congress had adopted the word *calorie* in spite of the fact that two distinct units were known by this name. Prof. Forbes and Mr. Preece suggested that it was not necessary to have a new unit at all, and that the heat which was the equivalent of the energy of one watt acting for one second, or the joule as it is sometimes called, should be taken as the unit of heat. They further suggested that the unit of temperature should be

Digitized by Google

that rise of temperature through which one gramme of water could be raised by the agency of an amount of heat of one joule. If the mechanical equivalent of heat is taken as 42,000,000 ergs or 4·2 joules, it is clear that this quantity of heat will raise one gramme of water 1°C., and that 1°C. is equal to 4·2 degrees of temperature on the new scale suggested.

Two objections can be raised to this proposal, one of which was mentioned at the time by the authors of the article. They referred to the fact that the mechanical equivalent of heat was not known with sufficient accuracy for this new unit of heat to be possible. The best determinations differed as much as two per cent. from one another at that time. This objection has now been removed by the careful and accurate research recently completed at Cambridge by Mr. E. H. Griffiths, of Sidney Sussex College, Cambridge. The value obtained by him for the mechanical equivalent was 41,940,000 ergs, or 4·194 joules, and this value very closely agrees with an independent determination recently published by Prof. Rowland.

There is, however, another objection to the adoption of the joule as an indirect unit of temperature, and this arises from the fact that the specific heat of water is not the same at all temperatures. The amount of heat needed to raise one gramme of water from 15°C. to 16°C. is different from that needed to raise it from 16°C. to 17°C., although the difference is but slight. Mr. Griffiths, in the course of his research, had to determine very carefully the specific heat of water at different temperatures, and found it to diminish by 0·026 per cent. for every degree centigrade rise of temperature. So that, assuming the specific heat of water at 15°C. to be unity, its value at any temperature t°C. is

$$1 - 0{\cdot}000266\,(t - 15).$$

It is therefore clear that if water is taken as the standard substance, it is not possible to define a unit of temperature, as that rise of temperature through which a unit quantity of water is raised by the absorption of a unit amount of heat.

It may be asked whether any substance does exist for which this definition would be applicable. The answer to this question is probably in the negative. Substances do not appear to behave uniformly in regard to the action of heat on them. It is well known that if several thermometers are made, in which the liquids used are different, the indications of these instruments differ in general from one another, although they may all be exactly alike at two particular temperatures. Even air thermometers, that is, thermometers in which the expansible substance is some permanent gas, differ from each other to a slight extent. The exact measurement of temperature is a matter of great difficulty; but even as long ago as 1854 Sir W. Thomson showed that it was possible, in accordance with the theories of thermo-dynamics, to determine the temperature of a body absolutely, without reference to the properties of any particular substance. The ideal perfect gas does not exist; but Sir W. Thomson showed how it was possible, by making certain experiments on the ordinary permanent gases, to deduce what the behaviour of a perfect gas would be, and thus to determine temperature in a manner independent of the peculiarities of any special substance. The value obtained by Mr. Griffiths for the specific heat of water at different temperatures is in the same way quite independent of the material used in his thermometers, since these have been calibrated in accordance with the absolute scale of temperature, and it does not appear that the suggestion of Prof. Forbes and Mr. Preece is applicable except to some ideal substance, although it may be true with sufficient approximation for most purposes.

THE ELECTRICAL CONCENTRATION OF VITRIOL.

BY BERTRAM BLOUNT, F.I.C., F.C.S.

For any operation which can be regarded as merely a question of the expenditure of a given number of heat units the use of an electric current obtained at its present cost is obviously absurd. But it is only by quitting the laboratory and entering the world where things are bought and sold that one can learn how indirect and slender is the influence of energy expenditure upon commercial cost. The discrepancy is unnatural and oftentimes deleterious to sound physical morality, but it exists and must be reckoned with. When read aright it may serve as a formative lesson instead of a disintegrating influence. It is only a half-truth that is paradoxical.

The reason why the proposition to use electrical energy for the concentration of vitriol is not fantastic, can be discerned when the conditions of the present process are considered. Vitriol in its most concentrated commercial form—for except by the process of freezing out ordinary concentrated acid or by adding the anhydride to the hydrated acid so as to bring it to the theoretical composition H_2SO_4, vitriol of 100 per cent. strength cannot be obtained—has a high boiling or rather decomposing point (338°C.), and is powerfully corrosive. These two properties increase the difficulty and cost of its concentration to an extent out of proportion to the amount of energy theoretically necessary to remove the superfluous water. The materials of which the vessels containing the acid to be concentrated can be constructed, are few; glass, porcelain and platinum practically exhaust the list. Now, in any system of heating by transmission through the walls of a vessel, a non-metallic material is at a disadvantage on account of its poor conductivity, which causes waste of heat and liability to fracture by the local strains set up on sudden and irregular change of temperature. It comes about, therefore, that platinum is generally preferred, in spite of its high price and the not inconsiderable corrosion to which it is liable. Recently an alteration of practice has set in, which is of especia[l] significance when considered in relation to concentration per[formed] electrically. Plant has been designed, consisting usuall[y] of a series of vessels of glass or porcelain arranged terrace-wise in which the heating is not strictly external, the series of vessel[s] being bodily enclosed in a flue, and the surface of the acid i[n] each, as well as the liquid dropping from one to the other, bein[g] exposed to a stream of hot gases, and being thereby robbed o[f] its surplus water. By this means the necessity for transmittin[g] every unit of heat through a refractory envelope is removed, o[r] at least diminished, and economy in energy and monetary cos[t] has naturally resulted.

Seeing that electrical heating, when judiciously performe[d] can be effected with an expenditure of current but little i[n] excess of that theoretically requisite, it is pertinent to enquir[e] what is the total quantity of heat, calculated from thermo[-] chemical data, needed to concentrate a given weight of sulphuri[c] acid of known strength. The whole question is ably discusse[d] by Herr A. H. Bucherer in a recent number of the *Chemiker Zeitung*, and the items of heat expenditure stated in detail. Assuming that 117 kilos of acid at 60°B. yield 100 kilos of the acid at 66°B., that being the highest grade usually made, and that the mean specific heat of the acid is 0·33, and adopting the usual values for the latent and specific heat of steam and for the heat of combination of the water originally present, with the acid from which it has to be expelled, the figure obtained for the quantity of heat necessary to concentrate the amount of acid mentioned above, is found to be 32,679 Cal., corresponding to 44·2 H.P. hours. This, at the rate of 4 pfennige per horse-power-hour, comes to 20 marks per metrical ton of concentrated acid, or, adopting the farthing rate upheld by Mr. Swinburne to a little over 10s. per English ton. Even the lower of these rates is distinctly high, and compares unfavourably with the cost of heat supplied directly from a furnace, the efficiency o[f] which must be low indeed to necessitate a similar expenditure. As has been already remarked, however, the cost of any metho[d] of concentration does not depend exclusively on that of the heat units required. Its merits must be judged as a whole.

The simplest way of applying electrical energy to the con[-] centration of sulphuric acid consists in passing a current which may be uni-direction or alternating, through a platinu[m] wire immersed in the acid, contained in a glass or porcelai[n] vessel, packed in non-conducting material to minimise the los[s] of heat by conduction and radiation. The voltage for eac[h] vessel must not be so great that the difference of potenti[al] between the point of entrance and that of exit of the platinu[m] wire is large enough to cause any appreciable electrolysi[s]. Provided the wire be disposed in the vessel in such a mann[er] that two points on it, the difference of potential of which [is] considerable, are not in juxtaposition, 5 volts per cell is n[ot]

Digitized by Google

... to prove excessive, particularly as the surface of the wire ... any case small, and the resistance of the electrolyte fairly ... In the event of loss by useless electrolysis proving to ... more formidable item in the account than appears ...le, an alternating current would have to be adopted. The temperature of the platinum wire may be taken as about ... above that of the acid which it is concentrating, whence it follows that, taking into consideration the specific resistance of platinum at 480°C., and its capacity for imparting heat to the medium (sulphuric acid) which surrounds a wire 0·5cm. in diameter and 77cm. in length would require a current of 364 amperes at a pressure of 5 volts to maintain its temperature, and would concentrate 24 kilos of ... in five hours.

The calculation of the cost of electrical concentration, when other items than energy are considered, can hardly be satisfactorily undertaken without the data afforded by large scale experiment. A comparison of the cost of the fuel needed, with coal at 10s. a ton, is, however, possible.

	Per ton of acid 66°B.
Electrical concentration	10s.
Direct heating	2s.
Theoretical cost	0·2s.

It is evident, therefore, that the advantages in other respects than fuel consumption would have to be shown to be very marked to counterbalance the high cost of electrical heating. A decision for or against the new system cannot be definitely announced; but on *primâ facie* grounds its economy is more than doubtful.

ELECTRIC TRACTION AT HIRSLANDEN.

With the object of steadying the load on the generating plant of an electric tramway, the Oerlikon Works have been led to try the use of accumulators at the power station. We have received a long description of the plant from Dr. Paul Schoop, in whose opinion this system presents many advantages. He says that it is well known that a saving of fuel is realised when steam engines work constantly at full load charging batteries, therefore avoiding the smaller efficiency of the engines at various loads. The first cost of plant, he says, is often the same in both cases, whether the plant is erected with or without a battery, the boilers, engines and dynamos being only one-third to one-half of the capacity with the battery combination.

We have often heard promises of this kind, but storage batteries in this country have never produced any results approaching this. Dr. Schoop assumes, however, that if a battery proves good enough with electric lighting it must prove better still with a tram line.

The plant for an ordinary trolley system for the line at Hirslanden consists of a steam engine of 50 H.P., with a corresponding boiler and a dynamo, giving about 60 to 65 amperes at 550 to 500 volts. The steam engines run at 250 to 300 revolutions, and the generators, compound-wound machines, run at 500 revolutions.

The steam consumption of the engine per horse-power hour is 30lb. at full load, 35lb. at half load, 40lb. at a quarter load, and 50lb. at one-eighth load. A slow-speed condensing engine (Sulzer, Winterthur) of 50 H.P. takes 17lb. steam per horse-power hour at full load and 23lb. at quarter load.

A battery of 270 cells (combining the features of the Oerlikon battery with those of the Tudor batteries) is used, each cell consisting of three positive plates (0·300 meter long and broad, and 8mm. thick), and four negative plates of the same size and thickness. The plates are hung in glass cells, and separated from each other by glass tubes of ¼in. diameter. The capacity of the battery is 140-150 ampere hours, and the battery stands a discharge of 35 amperes during three to four hours. The discharge may be 75 amperes during a little more than an hour if necessary. This battery therefore represents a reserve of 70 kilowatt hours (or 94 H.P. hours), and may discharge 37 kilowatts (or 50 H.P.) during an hour at least. If necessary, 110 kilowatts (or 75 H.P.) may be discharged, this figure being the maximum discharge for intervals of not more than five minutes.

The whole work on the tramline is therefore provided for a period of three hours from the battery alone, which suffices to carry on the work, and may, in case of any interruption or accident with the engine or dynamo, instantaneously be taken out of the battery. The generator, which need not be a compound-machine, but is preferably a shunt-dynamo, sends the negative current first through an automatic switch, which interrupts the circuit in case the battery tends to discharge back through the dynamo. The battery is directly connected to the line, the positive pole being connected to the overhead wire, whilst the negative pole goes to the rails, a safety-fuse and a line cut-out being provided. The last 81 cells near the negative pole of the battery are in connection with a regulating switch, having 28 contacts. A relay, placed between the overhead wire and the rails, brings into action an automatic regulating switch, which cuts cells in or out of circuit according to the demand for power.

Dr. Paul Schoop, in conclusion, gives a long list of the advantages of using a battery in this manner. Some of these are not very apparent, for example, "with the application of steam slow speed engines can be used, affording greater economy in fuel and less depreciation of the engine plant." That the building of high-speed engines has not received much attention in Germany is easily understood, but it is difficult to see what this has to do with the use of batteries. The principal advantage, perhaps, is that by the use of a battery it might be possible to employ water power for working a tram line under circumstances that would otherwise be impracticable. A constant supply of power, which would suffice for the mean power used during the day, would be unable to cope with the continual fluctuations due to the starting of cars.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, November 10th.

PHYSICAL SOCIETY.

5 p.m. (1) "On the Separation of Three Liquids by Fractional Distillation," by Prof. S. Young, F.R.S., Prof. Barrett, and Mr. Thomas. (2) "On the Critical Constants of various Ethers," by Prof. S. Young, F.R.S. (3) "An Instrument for Drawing Conic Sections," by J. Gillet, B.A.

THE JUNIOR ENGINEERING SOCIETY.

8 p.m. Inaugural Meeting, 13th Session. Mr. John Wolfe Barry, C.E., will deliver the Presidential Address at the Westminster Pal ce Hotel.

TUESDAY, November 14th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Address by Mr. Alfred Giles, President, and Presentation of Medals, Premiums and Prizes awarded at the close of last session.

WEDNESDAY, November 15th.

ROYAL METEOROLOGICAL SOCIETY.

8 p.m. Ordinary Meeting. (1) "The Great Drought of 1893 and its attendant Meteorological Phenomena," by Frederick J. Brodie, F.R.Met.Soc. (2) "Thunder and Hail Storms over England and the South of Scotland, July 8, 1893," by William Marriott, F.R.Met.Soc.

SOCIETY OF ARTS.

8 p.m. First Ordinary Meeting. Opening Address of the 140th Session by Sir Richard E. Webster, Q.C., M.P., Chairman of the Council.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. (1) "New British Freshwater Algæ," by Mr. W. West. (2) "On the Value of Aperture in Microscopical Research" (with lantern), by Mr. T. F. Smith. (3) "A Parasitic Disease in Flounders," by Mr. G. Sandeman.

THURSDAY, November 16th.

CHEMICAL SOCIETY.

8 p.m. (1) "The normal Butyl, Heptyl, and Octyl Esters of Active Glyceric Acid," by Percy Frankland, F.R.S.. and John MacGregor, M.A. (2) "The Ethereal Salts of Diacetyl-glyceric Acid in their relation to Optical Activity," by Prof. Frankland, F.R.S. and Mr. John MacGregor, M.A.; and other Papers.

The Electrician.

(The Oldest Electrical Journal.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street. London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Ready January 1.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

SPECIAL NOTICE.

With this number of "THE ELECTRICIAN" is issued (Gratis to Subscribers) a fine STEEL-PLATE PORTRAIT of Mr. JOSEPH WILSON SWAN.

Complaints of non-receipt should be promptly forwarded to the Publisher.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; and Joseph Wilson Swan, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

Last week's number of "THE ELECTRICIAN" commenced Vol. XXXII., and contained (Gratis) the Index to Volume XXXI.

NOW READY.

Volume XXXI. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

Cases for binding Volume XXXI., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

THE GLOW-LAMP MONOPOLY.

To-day witnesses the end, so far as Great Britain is concerned, of one of those commercial monopolies which have imposed themselves upon electrical enterprise. In the present instance, as in the case of the telephone, the monopoly was felt the more galling because it was known to be based on a legal fiction of the thinnest kind, a sort of judicially sanctified fraud against common sense. The patent which expires to-day was granted in 1879, one of those eventful years when invention and commercial enterprise were rapidly opening up the electrical industry. Those who think that electric lighting began only when JABLOCHKOFF lit up the Avenue de l'Opera in the summer of 1878 must have forgotten all the earlier forms of arc lamp, from the primitive device of STAITE down to the excellent lamps of SERRIN and LONTIN, still in use for light-

house illumination. Jablochkoff's simple "candle" indeed awoke men's minds to the wider possibilities which had existed already for some years in the mechanical generation of electric currents by the dynamos of Gramme and of Siemens. Across the Atlantic Wallace, Brush, and Elihu Thomson were already busy perfecting machinery and lamps for arc lighting, whilst in England, the original home of the arc lamp, Werdermann, Lane Fox, and Swan were at work in the field where Davy, Faraday, Staite, Holmes, Wheatstone, the Varleys, and Sir W. Siemens had been pioneers. Arc lighting for public squares was, indeed, comparatively well known, if little used, save for festivities like those of the marriage of the Prince of Wales in 1863, when London Bridge was lit up. But the general idea was that some way must be found for "subdividing" the too-brilliant light. Lighting by incandescence, as we now know it, was practically unknown outside the laboratory, though the platinum spiral lamp and the carbon-strip vacuum lamp had been suggested at various times. What the general enlightened knowledge of electric lighting was in August, 1878, may be seen from the Paper read in that month to the British Association by Mr. J. N. Shoolbred. There is no suggestion of the use of a distribution at uniform electric pressure with mains and branches, or of lamps of high resistance set in parallel. The first suggestion of any such system came in October of that year from Mr. Lane Fox, whose patent specifications bear witness to the accuracy with which he forecasts the requirements of the future system. To the use of high-resistance lamps in parallel were adjoined provisions that the luminous surface was to be relatively small, and proportional to the amount of light emitted; that the material should be refractory, of high specific resistance; that the ends of the luminous bridge should be thickened where they are clamped to the conducting wires: that the latter should be of platinum, passing through a glass globe, sealed into the glass; and that the globe should be exhausted by the aid of a mercurial pump and hermetically sealed. All these features he described in his patents. At the same date it was noised from across the Atlantic that Mr. Edison, then famous for his achievement in devising the phonographic reproduction of speech, had invented a new lamp which solved the problem of the indefinite subdivision of the electric light. Great was the sensation produced amongst the "bulls" and "bears" of the Stock Exchange. In spite of the advice of scientific men, a regular panic set in amongst gas shareholders; and stocks, at the end of October, sold at about half their previous value. When, a few months later, the secret of the Edison patent was revealed, it was greeted with the derision of the whole electrical community. A low-resistance spiral of platinum, not even in a vacuum, and with an automatic device to short-circuit it, lest it should melt and thereby extinguish all the other lamps in series with it, was the feeble cause of all this foolish panic. And the new dynamo which was to furnish current for the new lamp was to vibrate like a tuning-fork, instead of rotating! At the same time Swan, aided by Stearn, was improving the vacuum pump, and endeavouring to produce carbon bridges suitable for a durable vacuum lamp.

There was, in 1879, a general feverish expectation that something new and practical must shortly come forth. Edison kept the pot boiling with new ideas and vague descriptions of lamps. One by one the points enunciated by Lane Fox were appropriated into the Edison patents. The lamps originally proposed to be used in series were now represented in parallel; the high-resistance feature described in October, 1878, by Lane Fox was embodied by Edison in May, 1879, in a final specification to a patent which originally had been filed for low-resistance lamps. In February, 1879, Swan lectured upon and publicly exhibited a lamp constructed by himself and Stearn, having a carbon wire mounted upon platinum wires which passed through and were sealed into a glass globe which had been carefully exhausted of air. The successful public operation of this lamp caused even the New York journalists to chaff Mr. Edison upon his failure. Had Swan at this stage patented what he had attained to, he would have been unquestioned master of the situation. But with that modesty which characterises him he preferred to wait until he could point to some one really original feature. There was nothing new in carbon wires, or in vacuous globes with platinum wires sealed into them, or in using carbon in a vacuum. When early in 1880 he arrived at a novel point—the preparation of thin carbon bridges from "parchmentised" cotton thread, he at once patented the improvement. Nevertheless his lamp of February, 1879, contained all the essentials of the modern lamp. Its exhibition and successful operation ought to have for ever made it impossible for the monopoly of carbon vacuum lamps to fall into the hands of another and less scrupulously modest inventor. Carbon, the one element that answers the necessary conditions of infusibility and high specific resistance, was known, was triumphantly demonstrated to possess these qualities, was found not to waste away in the vacuous globe. Discovery of the properties, and invention of the combination were alike complete. Nothing remained, save to improve in detail the methods of manufacture of the various parts. Nevertheless, in November, 1879, a claim for this very combination was, by the astuteness of his patent agent, put forward on behalf of Edison, who had now abandoned platinum wires and betaken himself to the despised carbon. The notoriously-simple game of calling an old thing by a new name was once more played with success. Wires of carbon no thicker than one millimetre in fineness were already in commerce. To call a wire a wire would have been too plain. It was therefore re-christened as a "filament," as though it was a novelty. The absurdity of the whole thing ought to have been plain enough when years afterwards the lawyers of the Edison Company had to argue that the wire used by Swan in February, 1879 was a "stick" and not a "filament," notwithstanding which the Edison Company attacked the makers of the "Sunbeam" lamps for infringement, on the ground that the bridges of carbon in them (which were thicker than Swan's wire) were filaments! Mr. Justice Kay, before whom the most important of the various actions was tried, did indeed see through this unworthy device for seizing an invention by using a new name for an old thing, and gave judgment against the Edison claim. His decision was, however, upset in the Court of Appeal, though it would probably have been re-affirmed by the House of Lords had the matter gone so far. A judicious compromise of interests by the parties to the litigation prevented this appeal to the highest Court. Consequently, the Edison and Swan Company held, by this accident of law and the craftiness of patent draughting, the monopoly which expires to-day. It will scarcely console those who for the past five years have had to pay exorbitant prices for their lamps to learn that in no other country of Europe have the monopolists been permitted to build up a similar judicial fraud. Both in Germany and in France patents have been allowed to Mr. Edison for his particular way of constructing lamps; but not so as to give him a monopoly over Mr. Swan, whose prior success entitled him so obviously to something more than equal rights as an original inventor.

The crowning absurdity of the patent which expires to-day is that no lamp has ever been known to have been made in

Digitized by Google

accordance with its directions, except for purposes of litigation. Mr. Edison has not, so far as we know, been on unfriendly terms with the English Company. If he had had a "tar-putty filament" lamp in his possession it would have been worth one or two thousand pounds as evidence before Mr. Justice Kay; but we do not think it would have affected the judgment. Mr. Edison himself has not indeed profited much by the English monopoly (he is said to have received but one dividend, and that only recently); Mr. Swan, on the other hand, has, we understand, enjoyed a direct but an utterly inadequate reward. To Mr. Edison, however, in the eyes of the ordinary public, belongs the honour of having "invented the electric light."

We do not blame the Edison-Swan United Company for keeping up this delusion any more than for maintaining their monopoly. They acted on purely commercial lines; we are dealing with scientific history. The indomitable energy of the American inventor had started an electric light "system," and the Edison Company over here had simply to push it; they had, at first, to initiate nothing. To Major Flood Page belongs great credit for a uniform policy, not, of course, in the interests of science or of electric lighting, with which we are concerned, but which are nothing to him, but in the interests of the shareholders of the Company, for which non-shareholders, of course, do not care a rap. He succeeded by force of the ablest counsel in winning every law-suit, and without reducing the huge capital of the Company to pay off dividend after dividend until all arrears were clear. This was not done without some very severe dealings with small traders, whose business was not, perhaps, worth troubling about. The Company had the reputation of giving the smallest discounts, least credit, and no grace whatever when payment became due, but all this was in the interests of the shareholders, and by-gones are now by-gones.

To-day the least vestige of a connection between Mr. Edison and the invention of the carbon glow lamp is swept away. The clever composition of his patent No. 4,576 of 1879, and the still more clever handling of it by learned counsel, have kept up the legal fiction for the time appointed by our patent law. Now that the tar-putty patent is no more, nothing stands between Mr. J. W. Swan and the honour of the invention of the carbon glow lamp.

JOSEPH WILSON SWAN.

To-day (November 10, 1893) is eventful in electrical history as the date of the expiry of the master patent of the incandescent lamp with which the name of the subject of our portrait and sketch will for ever be closely identified. To Joseph Wilson Swan belongs the honour of having invented the carbon incandescent lamp, as well as of having perfected the process of its manufacture, although he unfortunately delayed in applying for a patent, and was thus, for legal purposes, forestalled by Mr. Edison.

Pirating a phrase of Wendell Holmes, Mr. Swan says he is 65 years young! To be exact, Joseph Wilson Swan's birthday was October 31, 1828. He is a native of Sunderland, was educated there, and lived there until his eighteenth year, when he removed to Newcastle-upon-Tyne. At Newcastle Mr. Swan spent the next thirty-five years of his life—chiefly in commercial pursuits. These were, for the most part, connected with chemistry, and did not prevent, but rather helped, Mr. Swan to keep in touch with progress in scientific discovery. It was during this time that he carried out the experimental work which culminated in the invention of his electric lamp. For the last twelve years he has resided at Bromley, Kent, where he has devoted himself entirely to research—chiefly in relation to electro-chemistry. Some of the results of this work were brought out at the lecture delivered by Mr. Swan at the Royal Institution last year.

Mr. Swan is what is popularly known as a self-made man, that is to say, he does not owe a very large debt of obligation to educational training. The days of his youth were not the days of physical science colleges. What scientific knowledge Mr. Swan acquired in early life, he acquired in spite of great difficulties and discouragements. Mr. Swan is a born inventor. The bias of his mind is essentially scientific and artistic, and his inventions, which are many, lie in these domains.

His name is known most widely in connection with the incandescent electric lamp. The first lamp ever publicly exhibited, having the typical features of the lamp which has done more than anything else to popularise electric lighting, was exhibited by Mr. Swan in 1879. Another of Mr. Swan's inventions (the carbon process) has made his name a household word among photographers all over the world, but the public do not so generally know that it is to Mr. Swan we owe this most excellent of all the permanent photographic processes for the facsimile reproduction of works of art. This was the outcome of the work and ideas of thirty years ago when Mr. Swan was greatly interested in the manufacture of collodion, a manufacture which he brought to a high state of perfection by means of an original method of making pyroxyline, which has never been published.

The world of art also owes to Mr. Swan, conjointly with Mr. Woodbury, the discovery of a new principle in mechanical printing, on which is based the process known as Woodbury-type. In applying photography to ordinary mechanical modes of printing, Mr. Swan was one of the first, if not *the* first, to recognise the necessity for changing the uniform character of the gradation of light and shade in a photograph to gradation of a different character adapted to the usual methods of mechanical printing. In a more or less modified and improved form, Mr. Swan's devices to this end—patented many years ago—are still employed, and their results are seen in the wonderful photogravure reproductions of pictures, which have done so much to familiarise the public with good works of art, and in the photographic block illustrations which are so frequently seen in periodical literature. The great revolution in the art of photography, which has made every other man, woman, and child a photographer, originated in the discovery by Mr. Swan of the now universally-known means of so greatly accelerating, by the action of heat, the sensitiveness of bromide of silver diffused through gelatine. Mr. Swan may justly be said to have created the modern "dry plate," though he did not publish his discovery except through the medium of a new manufacture, the secret of which very quickly spread in every direction.

Amongst the multitude of inventors associated with the improvement of the Planté-Faure secondary battery, it is apt to be forgotten that Mr. Swan was the originator of the cellular form of accumulator plate, and that it was he who first produced a miners' electric safety lamp, by a combination of his two inventions of the incandescent lamp and an improved secondary cell. We have not space to enter fully into descriptions of all Mr. Swan's inventions, but we cannot omit to mention his motor electric meter, which was one of the earliest of this type, nor his electric fire-damp detector.

Mr. Swan's latest achievement is the production of gold-leaf by electro-deposition, and, *àpropos* of this, he has been heard to remark, with a twinkle in his eye, that it was the only form of gold that had ever stuck to his fingers. The late President of the French Republic, and the University of Durham were amongst the foremost to publicly recognise the merits of Mr. Swan's invention of the incandescent lamp, the former creating him Chevalier of the Legion of Honour, and the latter conferring on him the degree of M.A., *honoris causa*.

A man of varied tastes and accomplishments, in literary matters Mr. Swan is critical and fastidious, and is a passionate lover of poetry. He has Tennyson by heart in every sense; nearly all the master wrote is as much in his mind as in his library. The anniversary of Mr. Swan's birthday has just passed, and we heartily wish him many happy returns.

REVIEWS.

A B C Five-Figure Logarithms for General Use. By C. J. WOODWARD, B.Sc. (London: E. and F. N. Spon, and others, 1893.)

This compact little book, which is neatly and conveniently put together, contains the common mantissæ of numbers up to 10,000, the logarithmic sines, cosines, tangents, cotangents to 10 seconds of arc, together with full explanations and simple exercises, showing how to use the tables. Not a little ingenuity has been exercised by the compiler in devising a system of arrangement, whereby the person who uses these tables may quickly and expeditiously arrive at the desired result. In the use of ordinary logarithm books there is much turning over of leaves before the desired page is found; and, where a lengthy calculation has to be made, the mere mechanical part of looking out the "logs" takes a great deal of time. Mr. Woodward has adopted the time-saving plan of providing each page with an index pip, after the manner of ledgers, index files, and memoranda books, so that the numbers to which the logarithms on the several pages relate can be seen at a glance and without having to turn to any page except the ones actually needed. Then again, there is an easy and efficient system of index letters on each page, enabling the user to quickly find the last figure in the mantissa in a subsidiary table at the bottom of each page. The book is divided into two parts, the first containing common logarithms of numbers, the second containing trigonometrical logarithmic quantities. To one who is already familiar with the use of tables, 10 minutes will suffice to enable him to work with Mr. Woodward's book, and he will find that a great many 10 minute's will before long be saved if he has occasion to use logarithms frequently.

Factory Accounts. By EMILE GARCKE and J. M. FELLS. Fourth Edition, revised and enlarged. (London: Crosby Lockwood and Co. 1893.)

On turning over the leaves of this work the first impression conveyed by the elaborate methods of bookkeeping which it describes is that any firm to whom it could be useful will already have adopted some system of its own, and that it would be hopeless for a small concern to introduce such complications into their business. But, apart from its value to accountants, there is much to be learned even by a very small firm from this, practically the only work on the subject. The authors touch here and there on questions of political economy, but the book is thoroughly practical, and the fact that it has reached its fourth edition shows that it has been properly appreciated. Some valuable appendices have been added.

Electric Lighting and Power Distribution. Part III. By W. PERREN MAYCOCK. (London: Whittaker and Co.)

We regret that the third and concluding part of this book in no way makes amends for the shortcomings of the first two parts. The author has characterised our review of the first part as "palpably unjust"; we therefore confine ourselves to three instances taken at random, on which we base our opinion of the present volume. A water voltameter is described on the third and fourth pages, but no information is given as to the volumes of gases given off; this is not scientific. In describing Planté's secondary battery the electrolyte is represented as consisting of one part of sulphuric acid in [illegible] parts of water, but nowhere in the sixteen pages devoted to modern secondary batteries is any further information given either as to the proportion of acid to water or as to the [illegible] of specific gravity of the electrolyte; this is not practical. A form of Goolden regulator is illustrated which has been superseded by an improvement some four or five years ago: this is careless. We hope that the work will be well pruned in any subsequent editions through which it may pass; it will then, as it is profusely illustrated and written in simple language, serve as a fairly good elementary textbook or a popular treatise for beginners.

Electric Light Fitting. By J. W. URQUHART. Second Edition. (London: Crosby Lockwood and Co. 1893.)

This book has been enlarged by the addition of chapters on street cable work, specifications, and fire risk. The sample specification is very poor; the chapter on fire risks consists of Mr. Heaphy's laws and "useful facts." The rest of the book is fairly up to date, but contains several suggestions of doubtful value. Combined switches and cut-outs are recommended, "reducing, as they do, the labour of fitting fuses." The author acknowledges that "many electricians will not permit the distribution of fuses throughout the system for house wiring. In such cases it is considered safer to assemble all the fuses upon a fuse board." While there are objections to scattering of fuses in unnecessary places, such as switches, it is certainly unwise to assemble *all* fuses upon a fuse board. It is suggested that the primary of a house transformer should be opened when all the lamps are switched off. "It may, of course, be effected by an automatic switch, but it is far more likely that a hand switch will prove the more reliable. The electricity user will be expected to do this himself, and will no doubt attend to it, *if the supply meter be upon the primary circuit of the transformer*." The italics are the author's. A statement of this kind is enough to shake confidence in the practical value of the whole of the rest of the book, which, however, contains a good deal of useful matter. A table of the resistance of wires is given, but no rules for selecting wires to give a desired fall of volts.

Mechanical Engineering Materials. By E. C. MARKS. 1893. Manchester: The Technical Publishing Company.

No objection can be taken to the small size of a pocket-book. The author chooses a size, and fills it with as much matter as it will hold. A treatise on the strength of materials and on the design of engineering construction, consisting of only 52 crown octavo pages, needs some excuse. This is to be found in the Preface. The author states that the contents "embrace the requirements of the City and Guilds of London Institute in a great part of one section of their annual examination in 'mechanical engineering.'" If we believed this statement, our opinion of the City and Guilds of London Institute would be considerably modified. The excuse, however, cannot justify the meagreness of the work. Not even all of the little it contains is useful. A paragraph on brass informs us that "about 35,000 persons, including men and women, boys and girls," are employed in the brass trade at Birmingham. Immediately facing this is a paragraph on delta metal, and we learn that the name "is but a name only, and in no way indicates either its properties or the purpose to which it may be suitably applied!"

Practical Electric Light Wiring. By F. C. ALLSOP. (London: Whittaker and Co. 1892)

In 270 pages, well illustrated, and containing nothing obsolete, the author does not manage to give a really complete account of the modern practice of wiring. The worst fault is that no wiring table or rules are given, except a table based on 1,000 amperes to the square inch. Nothing whatever is said about fall of volts. A diagram of the wiring of a house on the distributing board system, shows only one such board, in the entrance hall; pairs of conductors rise to each floor, and branch off to the rooms with no cut-outs at the joints. Another diagram of the tree system shows that method much more completely. Nothing is said about two-way switches for corridors, &c., or about three-groove moulding, which is in common use.

The Principles of Fitting. By a FOREMAN PATTERN MAKER. (London: Whittaker and Co.)

"No volume, that I am aware of," says the author, in his preface, "has yet been written upon the subject of Fitting." Very good reasons might be given for this gap in modern literature, and the present work fails to convince us that the art can be taught by a book. The substance of this book appeared as a series of articles in the *English Mechanic*, and will no doubt be appreciated by amateurs.

INDIAN TELEGRAPHS IN 1892-93.

The administration report of the above has lately been published in India, and reveals satisfactory progress. The Department has now 41,030 miles of line and 126,251 miles of wire, an increase in five years of 30 per cent. The amount expended on lines and buildings up to the current year is equivalent to about £5 millions. The lines, including cables, have cost about 992 rupees, or £62 per mile. In the year under review 2,405 miles of line have been added to the system. The number of offices have increased by 314, the total standing now at 2,553. This may seem a small number for a large empire, but the circumstances of Indian life are such that in towns and villages under 10,000 inhabitants the telegraph is little used. But the increase in 1892-93 of about 14 per cent. is significant of the demand that is arising for the wire for chiefly trading purposes. The revenue receipts show an increase of about £15,000 (at 10 rupees per £1), and the total revenue earned yields a return of 4·46 per cent. on the total capital outlay. The public may, therefore, rightly expect to look for the profit to be devoted to the provision of increased facilities. At the same time, since one-fifth of the entire revenue is made up of rent of lines on railways and canals, and the charges for these lines are notoriously high, no doubt the shareholders in the railways in question will think the time opportune for agitating for a reduction.

Foreign private messages have increased; but owing to reduction in transit rates, the revenue in this respect has not recovered to its former figure. The service between Bombay and Madras, in connection with the Eastern and Eastern Extension Telegraph Companies' cables, is as a rule excellent, although, as in the case of all land lines, occasionally interrupted by unusually severe storms. This important link in telegraphic communication with the Far East was one in the perfecting of which Sir A. J. Leppoc Cappel, when Director-General of Telegraphs in India, much interested himself.

Inland private messages have more than doubled in value and in number in nine years; the number in 1892-93 was nearly three millions. Here, again, the number is insignificant as compared with that of a European country, but it is not many years ago that a million of people in Calcutta despatched only 1,000 messages a day. The fact is that by far the greater part of the population of India is so poor that the expense of a telegram can rarely be indulged in.

Probably the intermittent character of the traffic accounts for the fact that no high-speed apparatus has before the current year been adopted. Hitherto hand-signalling and receiving by Morse sounder have been invariably in vogue, but the Wheatstone automatic apparatus has now been successfully used between Calcutta and Bombay at a speed of some 200 words per minute.

In the Government resolution dealing with the operations of the telegraphs, Mr. Bignell is specially mentioned for his services with the Isazai Expedition. This officer has had charge of the telegraphs in the Punjab for many years, and he has done valuable work in connection with many of the frontier campaigns.

In leaving India Lord Roberts expressed his obligations to Mr. Brooke, the Director-General of Telegraphs, and his establishment for the assistance rendered by them in military works.

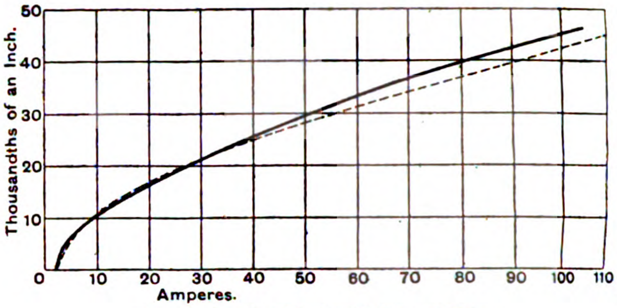
THE FUSING POINT OF COPPER WIRES.*

BY J. C. LINCOLN.

The accompanying figure shows a curve giving the relation between the fusing points and diameters of copper wire. The ordinates represent diameters in $\frac{1}{1000}$th of an inch, and the abscissæ the corresponding fusing currents.

The readings were taken under the following conditions:— The brass terminals in which the fuse was fastened were 5in. apart between their nearest points, and weighed 2oz. each; their shape was such that the wire was raised from three-fourths to one inch above the slate base. The room in which the experiments were made was guarded from draughts, and had a temperature of about 80°F. A Weston direct-reading ammeter was used in series with a rheostat and the fuse.

The points determined are plotted and the full curve drawn through their mean positions. A large number of readings was taken, giving a reliable character to the curve which, as will be seen, is a very fair one.



Curve showing Fusing Points of Wire.

The curve was found to have approximately the equatio $x=0{\cdot}14\,y^{1\cdot7}+2{\cdot}3$; the dotted curve is drawn to correspon exactly with this equation.

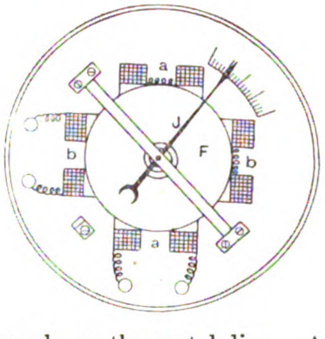
AN ALTERNATE-CURRENT PHASEMETER.*

The Allgemeine Elektrizitäts Gesellschaft has adopted, f the purpose of measuring the difference between the phases two alternating currents, the apparatus which is represented the accompanying figure. This instrument is constructed o metal disc, J, to which there is affixed a needle or poin which moves over a graduated scale. Two perpendicular co *a* and *b*, are traversed by the two alternating currents, p ducing a magnetic field which is so compounded as to exer



rotary action or couple on the metal disc. A spiral spring, opposes the rotation of the disc, and the point of equilibriu of the couple determines the position of the needle.

BOWDEN'S PATENT CABLE COUPLING.

Bowden's patent electric cable coupling was designed wit view to providing a convenient and safe means of divid high-pressure cables into sections, so that any portion of a m can be cut out and worked upon, without interfering with supply of current on the remaining portion of the cable. couplings are of small size, being about $4\frac{1}{4}$in. diameter at t largest part, and a pair of them lie easily in a surface bo ordinary size. By means of this appliance the main car severed in a few minutes and without risk to the operator makes a perfectly water-tight joint, and will work satisfacto even under water.

The illustrations show at Fig. 1 an outside view of coupling in its normal working condition; at Fig. 2 a vie it uncoupled, and having the rubber cup turned back so expose the inner coupling nut and render it accessible. F

Digitized by Google

shows the coupling disconnected, but having a rubber "dummy cup" connected to the end of the "live" main. Figs. 4 and 5 show a pair of couplings arranged in a street box. Fig. 6 shows one of the couplings held in a light wrought-iron clip by means of the projecting iron pins at the sides of the central

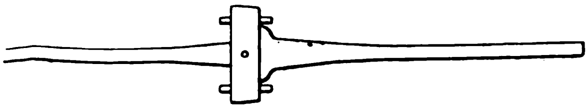

Fig. 1.

coupling ring, and in which position a curved spanner similar to that used for an ordinary hose-coupling is applied for screwing up or unscrewing the coupling ring. Coming to the actual construction of the coupling, it consists of two sets of coupling nuts, an inner one for connecting the ends of the conductors,

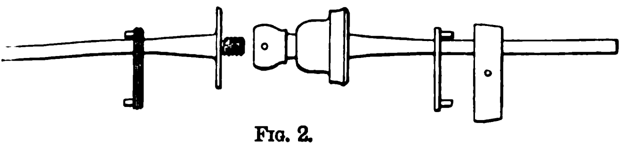

Fig. 2.

and an outer one for pressing together the enlarged and specially-formed ends of the rubber insulation. The rubber insulation takes the form on one end of the cable of a cup, and on the other end of a disc, each being made with a tubular neck, which slips on to the cable.

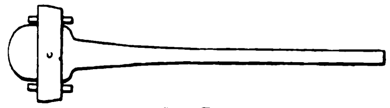

Fig. 3

The cup has a flange, the outer diameter of which is the same as that of the disc.

The central outer ring, which is of brass, is threaded inside at one end, and screws on to a brass washer or ring correspondingly threaded on its outer edge, which is shown hanging at

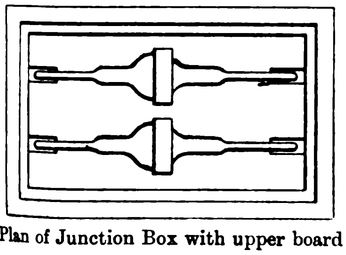

Fig. 4.—Plan of Junction Box with upper board removed.

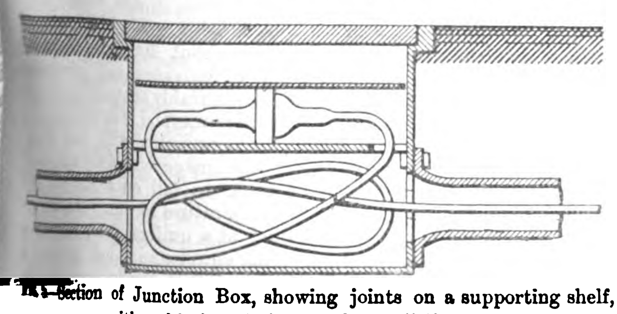
the left of Fig. 2, while it presses, by means of an internal flange, against the other brass washer shown hanging on the cable at the right of Fig. 2, between the rubber cup and the central coupling-ring. By this means the flange of the cup is tightly clamped against the disc, forming a water-tight joint.



—Section of Junction Box, showing joints on a supporting shelf, with a thin board above to keep off dirt.

The inner coupling arrangement consists of two male screws, right and left-handed respectively, which are bored to fit the copper portion of the cable, and sweated to its ends. A nut, tapped right and left hand to suit the screws, is fitted in such a manner that when turned sufficiently to separate the ends of the cables, as shown in Fig. 2, it can be turned no further, and consequently, cannot be accidentally unscrewed so as to drop. The nut is covered with rubber, so as to be insulated; it is easily turned by hand, but has two small holes to admit of the use of a wood-handled lever for tightening it to secure a perfect contact between the ends of the conductors. The coupling, which is supplied by Mr. William Boby, of Union-court, London, is provided with about 3ft. 6in. length of cable, and the cup and disc are put on at the same time as, and virtually form one piece with, the rubber insulation of the cable.

The House-to-House Electric Light Company, of West Brompton, have had the couplings in use for about eighteen

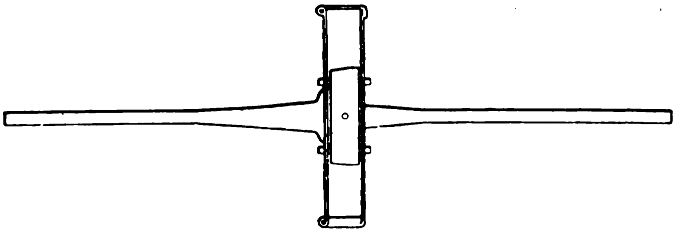


Fig. 6.

months, and find them satisfactory. The electrical contact seems perfect, and they find the appliance a great convenience; they have about 70 in operation.

The Electricity Supply Company of Spain put 12 into their mains as a trial, with the result that 100 are now in course of construction for them. Forty of the couplings have been supplied to the City of London Electric Light Company.

ELECTRIC PYROMETRY.*

A new phase in the history of the measurement of high temperatures began with the work of Sir William Siemens, who showed that the variations in the electrical resistance of a heated metallic conductor would afford a pyrometric method. The names of Muller, Quincke, and Ressig may be mentioned in connection with early work in this direction, but Siemens was the first to demonstrate the practical nature of the method. The first notice I can find of his experiments is given in a letter to Dr. Tyndall, dated December, 1860. Twelve years later, in a lecture delivered before the members of the Royal Institution,† Siemens made some interesting remarks on the industrial aspect of pyrometry as limited by capabilities of the mercurial thermometer. He said, "when we ascend the scale of intensity, we soon approach a point at which mercury boils, and from that point upwards we are left without a reliable guide; and the result is that we find in chemical books on chemical processes statements to the effect that such and such a reaction takes place at a 'dull red,' such another at a 'bright red,' or a 'cherry red,' or a 'white heat,' expressions which remind one," he adds, "of the days of alchemy rather than chemical science at the present day." With reference to this it may be observed that if, as Sir William says, technical men "were left without a reliable guide," directly the limits of the mercurial thermometer were passed it was their own fault. The thermo-couples proposed by Becquerel and others would have given them trustworthy measurements of high temperature, but they either lacked knowledge of the sources of information or the skill to use the far from complicated appliances at command. An excellent dead-beat galvanometer, so essential in connection with all pyrometric methods of which electricity is the base, was long ago provided by Sturgeon; but metallurgists, who sadly needed a good pyrometer, were either ignorant of the existence of such physical instruments, or untrained in their use, and are now only beginning to recognise the necessity for their adoption.

The nature of Siemens's instruments may be made clear by the accompanying diagram (Fig. 1). A divided current passes from the battery, B, to a platinum wire, C, coiled round a clay cylinder, and to a resistance coil, R. At the ordinary temperature, the resistance of the platinum coil is balanced by the standard resistance, R. If, however, the platinum coil be heated, the resistance will be increased, and this increase of resistance, which can be measured in various ways, indicates the temperature of the coil C. The coil itself may be adequately protected and exposed to temperatures,

* Abstract of a lecture on "Alloys," by Prof. W. Chandler Roberts Austen, before the Society of Arts, March 6, 1893.

† *Proc. Roy. Inst.*, Vol. VI. p. 483.

Digitized by Google

which have been determined by the air thermometer; the deflection of a suitable (differential) galvanometer, G, will then indicate temperatures directly. For instance, the temperature at which zinc boils has been accurately fixed at 940°C., and if the coil is heated in the vapour of boiling zinc, the angle through which the galvanometer mirror is deflected marks the temperature of 940°C. For many years this electrical-resistance pyrometer was the only appliance believed to be trustworthy which could be placed in the hands of artificers. Its usefulness was widely recognised, and a Committee of the British Association was appointed to report upon it. The result of the inquiry* rather tended to shake confidence in the instrument, as it was shown that it was liable to changes of zero. Mr. H. L. Callendar† has, however, done admirable service by proving that, with certain precautions, the method may be rendered trustworthy. He winds the platinum wire on a plate of mica, excludes reducing gases (as the Committee suggested) by enclosing the coil in a tube of doubly-glazed porcelain, and uses a

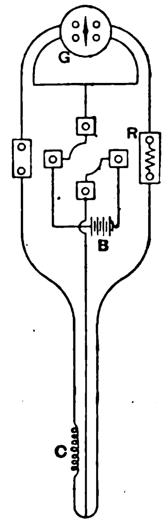

FIG. 1.

zero method of measuring the current with the galvanometer. It will have been evident from the works of the Becquerels and of Deville that by the year 1880 two main systems of pyrometry had been well established; these depended respectively on the use of the air thermometer and of thermo-couples. Siemens's electrical pyrometer, though its utility was admitted, was expensive, and confidence in it was not established. The basis of optical pyrometry had been firmly laid, but the measurement of high temperatures by optical methods had not passed into the domain of industrial work. The publication of the article "Pyrometry," in the last edition of the "Encyclopædia Britannica," in 1886, enables us to judge what progress has been attained at the period when this important work appeared. In 1886, the author of that article, Mr. N. Shaw, who is so eminently qualified to form an opinion, took a distinctly gloomy view of pyrometry. He concludes his

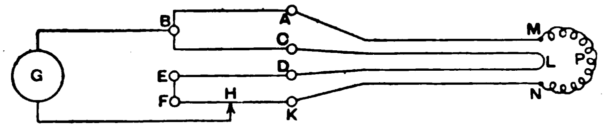

FIG. 2.

excellent article by suggesting doubt whether any of the instruments he describes "can be easily made to take up the temperature of the body or enclosure under investigation," and he points out that "perhaps the most important modern attempts at the development of pyrometry are those connected with the identification of the law connecting the temperature with the amount and nature of energy which it radiates, for on such attempts depends the possibility of measuring the temperature of a hot body by means of the light it emits" . . . . and he adds that, "at present there is no general agreement between scientific men as to the form the relation takes." In 1886, the year Shaw wrote, the beginnings of very distinct advances in practical pyrometry were made. Callendar published the first part of the work that are subsequently developed in his well-known Paper,‡ which restored confidence in the electrical resistance pyrometer. In the following

* "British Association Report," 1874, p. 242.
† *Phil. Trans.*, Royal Soc., Vol. CLXXVIII., 1887, p. 161, and subsequent Papers in the *Phil. Mag.* and *Proc. Roy. Soc.*
‡ *Phil. Trans. Roy. Soc.*, loc cit.

year Prof. H. le Chatelier* communicated a Paper to the Chemical Society of Paris on the platinum, platinum-rhodium thermo-couple, which gave an entirely new and vigorous impulse to thermo-electric methods of pyrometry, as the form of thermo-couple he employed takes up the temperature of the locality in which it is placed with astonishing rapidity, and Barus established the thoroughly trustworthy character of the platinum, platinum-*iridium* couple, and devised a very ingenious pyrometric method depending on the viscosity of gases.

Fig. 2 represents, somewhat diagrammatically, the arrangement of Callendar's apparatus.† A B, B C, are equal resistances, forming the arms of the balance. The battery is connected at A and C, and one terminal of the galvanometer, G and B; D E represents a set of resistance coils, which, together with the resistances, A B and B C, may be supplied by an ordinary box of coils of the "Post Office" pattern. F K represents a straight bridge wire, with a divided scale attached. The other terminal of the galvanometer is connected to the contact-piece, H, which slides along this wire. The leads, A M, K N, from the pyrometer coil, P, are connected to A and K; and the compensating leads, C L, L D, the resistance of which is equal to A M, K N, are connected to C and D. These four leads may be of any convenient length; they are symmetrically arranged, so that corresponding parts are always at the same temperature. When the balance is found by inserting suitable resistances in the arm, D E, and sliding the contact-piece, H, it is plain that, since the resistances, A B, B C are equal, the resistance of the pyrometer and its leads, together with that of the length, H K, of the bridge-wire, will be equal to the remaining portion, F H, of the bridge-wire, together with the coils, D E, and the compensating wires, C L D. Thus the changes of the resistance of the pyrometer-leads, A M, K N, are compensated by the equal changes in the leads C L, L D, and the resistance of the pyrometer-coil itself is directly given by the sum of the coils D E, and the reading of the bridge-wire. The resistance of a centimetre of the bridge-wire F K is made to correspond to such an increase of the resistance of the pyrometer-coil P as is produced by a rise of 1°C. The contact key H slides along this wire, and the galvanometer can easily be made sensitive to $\frac{1}{100}$th of a centimetre of this bridge-wire, so that $\frac{1}{10}$th of a centimetre, which corresponds to $\frac{1}{10}$th of a degree, can, of course, be measured with certainty. The author has worked for several days at the Royal Mint with Mr. Callendar, and is satisfied that at temperatures exceeding that of bright redness the comparative readings are accurate to $\frac{1}{10}$th of a degree. This would have been considered impossible a few years ago, and the statement will, perhaps, be received with some incredulity.

The reader will, however, remember that measuring the increased resistance of a heated conductor is not the only way in which electricity has been made serviceable in the measurement of high temperatures. It has long been known that if a junction of two metals be heated, the electrical equilibrium of the system is disturbed, and the measurement of the difference of potential produced affords a means of estimating the temperature of the junction. The use of such thermo-junctions appears, as has already been stated, to have been suggested by A. C. Becquerel in 1826, and adopted by Pouillet ten years later. Unfortunately, the metals composing the thermo-junctions were badly chosen, and their use was consequently greatly retarded until, as already stated, within the last few years, Prof. H. Le Chatelier, of Paris, advocated the use of platinum, in conjunction with platinum alloyed with 10 per cent. of rhodium. The author first adopted this couple in 1889, and has since constantly used it, in conjunction with a photographic recorder, devised for the purposes of an investigation which was entrusted to him by the Institution of Mechanical Engineers. This instrument will be described presently. In its latest form, the couple consists of two wires, one of platinum and the other of platinum-rhodium alloy, mentioned above, simply twisted at their ends or soldered with gold, and connected with a dead-beat galvanometer of about 200 ohms resistance. The Deprez and d'Arsonval form of galvanometer, particularly the latest type of this instrument, is admirably adapted for use with the thermo-couple. A photographic method was employed as early as 1887 by H. le Chatelier‡ in connection with his thermo-couple. It consisted in allowing the image of induction sparks, produced at regular intervals of time, to fall on a narrow fixed sensitised strip of glass. If the temperature to which the thermo-couple is exposed is rising or falling at a uniform rate, the photographic images of the sparks will be equidistant; but if there is at any moment an arrest in the rise or fall of the temperature, the images of the sparks will then be closer together. The distance between the individual lines affords a method for measuring the rate at which a thermo-couple receives or loses heat from any hot locality or substance in which it may be placed.

The new departure in pyrometry, by which curves are automatically obtained, will now be described. It will be obvious that by confining the image of the mirror to a minute spot, and by moving the sensitised plate at a uniform rate, a time-temperature curve may be traced by the aid of photography. The author is satisfied that the thermo-junction can afford trustworthy results, accurate to 1deg., at temperatures of over 1,000°C. One important feature of the appliance is the minuteness of the space occupied by the thermo-junction, which may be suitably protected, and inserted into the midst of a very small mass of metal. The pyrometer is calibrated by exposing the thermo-junction to certain known temperatures, such as the solidifying points of salts or metals. There is no difficulty in recognising the melting or solidifying points; for, as the mass passes from the solid to the fluid state, the temperature remains constant for a brief period, the duration of which depends on the amount of material operated upon, and its latent heat of fusion; the result being that the spot of light from the galvanometer will be arrested, and the position on the scale at which it stops marks the temperature to be determined.

POWER-HOUSE ENGINES.*

The subject of "Power-House Engines for Electric Railways" embraces one of the most important and interesting subjects that street railway companies have to consider in the equipment of a power plant. The subject represents the vital part of a street railway; as the heart forces the life current through the arteries of the body, and an impairment or weakness of this vital organ will produce impaired health, so also is the power-house engine the vital part of the street railway, as it produces the power that creates and forces the electric current through the arteries (the trolly wire) of the electric railway, and, like the heart, if the engine regulates badly, it produces a bad circulation of varied potential, which impairs the service of the road. The variety of opinion, as to the best kind of an engine for street railway power, makes the subject a difficult one on which to reach a conclusion that would not be criticised, and this Committee will therefore endeavour to treat the subject impartially. The most essential points to be considered are as follows:—

(1) Perfect regulation.
(2) Highest economy.
(3) Greatest durability.
(4) Division of power into units.

(1) *Perfect Regulation.*

Good service and uniform speed of cars can only be maintained by a constant, unvarying potential, and in order to do this the engine must regulate practically perfectly, so that there will be no variation of speed as the load varies. The variation of power required on an electric railway is unquestionably considerable, caused by cars constantly stopping and starting, going up and down grade, rounding curves, using resistance in order to run slow through crowded streets (which necessarily increases the load) and in order to have perfect service, and uniform speed of cars, the engine must be constructed so as to maintain a constant and uniform speed under any variation of load. This variation of load amounts to a very considerable fraction of the whole maximum load; in small plants it may reach 95 per cent. of the maximum, and in large plants is frequently 50 per cent. If the speed of the engine decreases when a heavy load comes on, the potential is reduced, which consequently reduces the speed of the cars, and creates an extra strain upon the machinery, which, of course, means an increase in the consumption of fuel, and in various other ways produces an imperfect and expensive service. If the speed of the engine increases, when the load diminishes, it consequently increases the voltage or potential, which is liable to result disastrously to the generators and car motors. Moreover, if the engine regulates badly, and the load diminishes suddenly, the engine is liable to "race." The governor, or regulator, to be mechanically perfect should be so constructed as to control the engine under any variation of load, with a variation of speed not to exceed 2 per cent. An engine that will regulate within 2 per cent. is practically perfect for street railway work, though there are engines on the market that, on electric railroad service, can be held to 1 per cent. deviation from the mean speed. The governor should be constructed so as to be easy of access to all of its parts, and capable of being oiled while the engine is running. Particular attention should be given to the construction of the governor, to see that there are no weak parts, and it should be simply constructed. The range of cut-off must also be larger than in engines for less variable load. The cut-off should be easily regulated between the limits of $\frac{1}{10}$th and $\frac{7}{10}$ths of the stroke. The severe conditions of high speed, and sudden and extreme variations of load, make it especially important that the engine have the best possible construction, with extra weight in flywheel and bed-plate, and that the foundation be more than usually substantial.

One of the most important features to be observed, in order to maintain perfect regulation, is to place the engine in the hands of a competent engineer, who is capable of adjusting and keeping the engine in good running order; a good engine or piece of machinery, placed in the hands of an incompetent person, will never give good service or economical results, and no doubt in a large number of cases, where engines do not give good service, the expense of maintenance is high, and perhaps a large number of the frequent casualties are attributable to incompetent, careless, or negligent engineers.

(2) *Highest Economy.*

The matter of economy has been exhaustively discussed from a scientific standpoint in the various periodicals, as well as before the learned societies, and this Committee feels inadequate to the task of presenting a report that will not be a repetition of the records on the subject. The Committee will, therefore, not undertake to deal with the subject in an elaborate and scientific manner, but will endeavour to give a few practical hints that will be of interest. The economy of an engine is dependent, to a great extent, on other parts of the power plant, and it will, therefore, be proper to discuss the matter in all its phases, even though it may be a slight digression from the subject proper, as economy is the most important factor in the operation of a power plant. In order to obtain the highest economy in the operation of an engine, it is necessary to have the engine properly adjusted to its load. It is a fixed principle that the highest engine efficiency results in working the engine constantly at its maximum rated capacity; underloading and overloading are each, therefore, undesirable, though the compound condensing engines of the largest stations will stand underloading better than the simple high-speed engine, and both classes of engines will stand underloading better than overloading. There should then be ample power both in boilers and engines to obviate excessive overloading as well as to provide for contingent breakdowns or needed repairs. The packing should be kept intact, valves free of leaks, cylinder perfectly smooth and true in diameter, so that there will be no loss of live steam. The cylinders and bearings should be kept well lubricated, and one of the most important factors is to have the steam enter the engine at a steady pressure at all times. Careful attention should be given to the setting of the valves so that the cut-off will be the same at both ends of the cylinder. The engines should be set in the closest proximity to the boiler so as to require the least amount of steam pipe, as the longer the steam pipe the greater is the loss by condensation. The steam pipe should be covered with one of the best non-conducting materials, of which there are several on the market, so as to reduce to the minimum the loss by conduction, radiation, and consequent condensation. Flexible joints should be used to prevent leaks at the joints from expansion and contraction. It should be borne in mind that wherever there is a leak of steam there is a loss of money.

We are so accustomed to consider the reciprocating engine as the only steam motor within our reach that it is not surprising that a new form of steam motor should have quietly been developed without our notice. The Committee refers to the steam turbine, one form of which, the Parsons steam turbine, has recently been subjected to vigorous and searching trials and tests by Prof. A. B. Kennedy, of London, England, which has developed power at the rate of $20\frac{3}{10}$lb. of water per electrical horse-power per hour in a turbine using steam at 97lb. per square inch, and making 4,600 revolutions per minute, the turbine having a capacity of about 165 H.P. The small size of this motor, absence of reciprocal motion, and consequent independence of heavy foundation, high speed of rotation, and consequent availability for gearing direct to generator, simplicity of construction and consequent low cost, and its very high efficiency as a motor, all tend to make this a strong rival to the reciprocating engine as a steam motor for electric power and light stations.

The next point to consider is the boiler room, where the steam is generated. Engines may be of the very best type, and, together with the steam pipe, may be in perfect condition; but unless the boiler room receives the proper attention there will be dollars lost where cents are saved in the engine room. The design and proper construction of the boiler plant is quite as essential to economy as is the case with the engine. The boiler plant should have ample capacity, as there are few cases when the draught and setting are so excellent as to allow heavy forcing without a serious loss of economy. A raising of the evaporation from $6\frac{1}{2}$lb. to 7lb. of water per pound of coal represents the saving of about 7 per cent. of the coal bill, which would warrant the incurrence of an expenditure for improvements equal to one whole year's coal bill. The boilers should be equipped with good boiler-cleaners, and should be inspected regularly and kept free of scale; the flues should be kept clean and boiler walls intact.

* Abstract of Report of Committee to the American Street Railway Association at the Milwaukee Meeting.

Digitized by Google

Fuel is one of the largest items of expense attached to a power-house, and the waste of fuel by incompetent firemen is one of the greatest leaks attached to the operating expenses ; it is a safe proposition to state that an incompetent fireman will waste enough fuel in a year to assist very materially in paying a dividend. Simply the act of pitching a shovel of coal does not qualify a man as a fireman. It requires skill and intelligence. There is a natural disposition among the labouring classes to endeavour to do their work with the least amount of labour ; and, as a rule, the fireman will fill his furnace half full of coal at one time, give it a stir with a poker, and then set down and rest until time to fill it up again, instead of firing frequently, maintaining a light fire, and scattering each shovel of coal evenly over the grate bars, by which the maximum amount of heat can be obtained from the least amount of coal. A good plan to encourage economy on the part of the fireman is to pay him a coal premium at the end of each month, basing the amount of the premium paid on the average number of bushels of coal consumed each day during the month for a certain number of cars run. This plan was adopted by the Chairman of this Committee, about two years ago, with very satisfactory results. The limit on the average number of bushels consumed per day, to secure a premium, was placed at a point that required skill and economy on the part of the fireman to keep within the limit. During the past two years they have succeeded in obtaining the premium about one-half of the time. Careful firing is a good smoke preventive. No matter if the draught is good, and the best quality of bituminous coal is used, unless the coal enters the fire-box in the proper manner, there will be more or less black smoke issue from the stack, representing a lack of combustion and waste of fuel. Careful firing preserves the boiler and saves coal, gives a steady steam pressure, which secures an economical point of cut-off, and steam economy, from a proper expansion in the cylinder. When the plant is of such size as to require more than two firemen it will always be good economy to employ mechanical stokers; aside from their saving in labour account, they economise fuel, insure uniformity of steaming, prevent the chilling and straining of crown sheets by in-rushes of cold air through the fire doors, and prevent smoke.

The use of oil as fuel in place of coal is a live question with power and light station engineers and managers. Actual trial of oil, keeping accurate records of costs and results, will be the only absolute answer to the important question, "*Does it pay?*" But as an oil installation is somewhat costly as an experiment, it is best to secure as full outside evidence as possible on the question as to the *probable* economy. Fortunately, several accurate comparisons have been made with sufficient care and accuracy to make them valuable witnesses. Probably the most complete evidence of this kind comes from a recent and exhaustive test of the power plant of the Twin City Rapid Transit Company of Minneapolis and St. Paul (Minn.), made by Messrs. Wm. A. Pike, of Minneapolis, and T. W. Hugo, of Duluth (Wis.). On the comparative value of the two fuels, coal and oil, this test showed that with ordinary Lima oil, weighing $6\frac{3}{10}$lb. per gallon, and costing $2\frac{1}{4}$ cents per gallon, and coal that gave evaporation of $7\frac{1}{2}$lb. of water per lb. of coal, the two fuels were equally economical when the price of coal was $3.85 per ton of 2,000lb. With the same coal at $2 per ton the coal was 37 per cent. more economical, and with the coal at $4.85 per ton the coal was 20 per cent. more expensive than the oil. These results include the difference in the cost of handling the coal ashes and oil. The oil used gave the following as the result of the average of five chemical analyses :—

Hydrogen, 13·03 per cent.
Carbon, 82·38 per cent.

Evaporation, 20·631b. of water from and at 212°F. per lb. of oil.

The average plant is not run at anything like a minimum expense. So long as the cars keep running little attention is paid to the efficiency and economy of the power plant. The obvious and intelligent way to get the most work out of a steam plant at the least expenditure is to ascertain first how the total expenditure, chargeable to power per unit of production, compares with other street railroads ; of course, in making a comparison of this kind, the difference between the surrounding conditions of each plant should be considered. After making the comparison, if the plant is not running as economically as other plants, then such tests and investigations should be made as to ascertain separately the condition of the boilers and engines. To do this it will be necessary to furnish the station engineer with full facilities for testing and maintaining records of each part of the station plant and operation, it being presumed that only an engineer competent to carry out such tests and records will be placed in charge of the plant. If you find the plant is deficient in any part do not adopt haphazard the first idea that suggests itself for its improvement, but study out the cause of the trouble. If the boilers are inefficient it may be because the rate of combustion is too high or too low for the amount of heating surface, a faulty setting, a poor heater, or none at all, a wasteful fireman, or any one or more of a dozen different causes ; the engine may be of inefficient type, underloaded, overloaded, badly set or leaking. Find the trouble and then go systematically to work and remedy it. The standard of maximum efficiency attainable should be ascertained with each portion of the plant, and each part brought up to that standard. With modern appliances and fairly well constructed plants a total station efficiency of 70 per cent. should be set as the standard.

The loss of power between the engine and switchboard terminals is from 15 to 25 per cent., which is attributable to the inefficiency of dynamos, and also to the friction of countershafts, belts, idlers, and attachments, which are simply power consumers, representing a waste of power without any resultant benefit. Besides the loss of power, the expense of maintaining the various arrangements for the transmission of power is quite considerable. This waste of power can be overcome by connecting the generator direct to the shaft of the engine. While machinery of this class is more expensive than the other because it demands a slow speed for the generator, necessarily increasing its size, the saving in power and maintenance of the machinery of transmission will be sufficient to compensate for the slightly reduced dynamo efficiency, due to slower rotation, and will warrant the recommendation of the direct-driven equipment for moderate or large-sized plants. This direct coupling of engine and generator gives also an important advantage, particularly in the large stations in crowded cities, by the considerable saving in floor space.

The Committee look with favour upon compound engines for street railway work, especially so with engines having ranges of cut-off which keep the low pressure cylinders ever from expanding below atmosphere. When this is the case there is no doubt that the compound engine is very economical as it carries the expansion of steam to a greater limit. Where it is possible to condense in connection with the compound engine, there is not the slightest question as to economy. In fact where condensing is possible there is no reason why the expansion should not be carried to a further limit. Ordinary considerations of economy in labour account will dictate the use of labour-saving appliances and methods about the boiler house and engine room. A feature frequently omitted, owing to a lack of appreciation of its value as a labour saving and a safety appliance, is a light overhead travelling crane with differential pulley blocks for handling armatures, cylinder heads, and other parts of machinery.

The practice occasionally followed of placing the generators in the second storey of the power-house, is not to be recommended even where floor space is difficult to secure. The difficulty of securing for the dynamos rigid foundations, and the resulting evil of increased frictional losses and heating, will generally render the disposal of plant inferior to placing the dynamos on rigid ground foundations, even if the problem of floor room has to be settled by direct coupling of generators to the engine or the incurring of considerable outlay for additional ground room. The plan adopted at the power station of the West End Company in Boston of sinking the countershaft into a basement pit, keeping the generators on the same floor with the engines, is worthy of consideration for extraordinarily large plants as securing rigidity of foundations, necessary belt lengths, economy of floor space, without going to direct gearing of generators to engines.

(3) *Greatest Durability.*

When electric traction was first introduced for street railway engine builders were not cognisant of the actual requirements of this kind of service; they did not anticipate fully the extraordinary variation of load and the liability of a short circuit, which so severely test the strength of an engine. They proceeded to build engines from theoretical plans and specifications which have proved by actual practice to be entirely inadequate for this class of work. Engine builders, however, are endeavouring to overcome mistakes which were made at the outset by strengthening and making all of the parts more durable, and to make such improvements as will meet all the demands for this extraordinary class of work.

(4) *Division of Power into Units.*

When electricity was first introduced as a motive power for street railways the largest type of generators were small units as compared with those manufactured at the present time ; and, as a rule, high-speed engines from 100 H.P. to 200 H.P., belted direct to the generator, were in most cases adopted without regard to the size of the plant. In some instances Corliss engines were installed and the dynamos connected to the countershaft. In nearly every installation mistakes of more or less proportion were made, not due, however, to the fault of street railway people, but the lack of knowledge on the part of the manufacturer as to what was actually necessary to properly fulfil the requirements of the new field of traction. The pioneers of electric traction have, as a rule, suffered from these mistakes by the expense of changing to modern, improved, and more economical machinery, or have been financially compelled to jog along with the obsolete outfit and consequent large power-house expense. Local surrounding and conditions will, to some extent, govern the division of power into units, but as a rule, the following principle will be safe to follow :—The size of the proper unit of subdivision should be such as to give th

Digitized by Google

required relay or reserve above the maximum power adopted. This will apply equally to boilers, engines, and dynamos. The following table will serve to show approximately the proper proportion :—

Maximum horse-power required to operate road.	Number of engines required.	Horse-power of each engine.
200	2	200
400	3	200
600	3	300
1,000	3	500
1,500	4	500
2,000	4	750

It will be observed from the above table that enough engines are provided to furnish the maximum horse-power required to operate a road and have a surplus of one engine. This is very essential, as it enables the engineer to keep his engines in perfect adjustment and repair, having at all times an extra engine to work on, or in case of a breakdown the extra engine is ready to take the place of the disabled one. The "maximum horse-power required to operate the road," referred to in the table, is not to be taken as the sum of the power needed by each car in service, except in case of small installations, since the maximum power required does not increase in proportion to the number of cars in use, since the line losses are not materially increased with increased traffic, and because as the number of cars increases, the fluctuations of load tend to balance themselves and to reduce the *maximum* load nearer to the *average* load. Thus in a ten-car plant, cases will occasionally occur when all of the cars will require their full power at the same time, and the power plant must be planned accordingly, but there is no probability that all of the cars of a one-hundred car plant will all require their full power at the same time ; from 60 to 75 per cent. of this power, depending upon local conditions, will be sufficient for this plant.

Conclusion.

The Committee sent a list of questions to a number of street railways for such information as would be of service in formulating an intelligent report, by securing an idea of the construction and equipment of the various power plants, and the result of their operation and experience with the various types of engines in service. Only a small number made a reply, from which the Committee would infer that a number of roads are not giving the question of the expense of their power-house much consideration. From the replies that were received, the Committee find quite a variety of types and kinds of engines in use by street railroads, and no uniformity of opinion as to the best and most economical engine for power-house work. Question No. 30 on the list was "What kind and style of engine would you recommend for railway power use (base your opinion on regulation, efficiency and economy)?" In nearly every instance the kind and style of engine which the particular railway had in service was always recommended as the best, showing that the observations and investigations as regards their power were restricted to their own power plant, and the result of its operation was accepted as perfectly satisfactory, perhaps without making comparison with other plants or making such tests and investigations as are necessary to ascertain if they were obtaining a standard of efficiency from their plant. The Committee therefore feel at liberty to express their own convictions as to the best engine for power-house work, based upon the investigations which they have made, and in the line with the progress of the present time.

In selecting a type of engine the size of the plant must largely govern, as well as local conditions, such as water supply and price of fuel, though some consideration may be given to opportunities for station room and arrangement. For small plants to run 10 or 15 cars, simple high-speed engines belted direct to generators are unquestionably the proper choice. For 20 to 50-car plants, compound engines, with condensing apparatus where it is possible ; with tandem compound engines for the smaller plants and cross compound engines for the larger ones, geared direct to generator, will probably be found most economical. While for the larger systems compound or triple-expansion condensing engines, using steam at a high initial pressure, and either driving a countershaft or coupled direct to generator, whichever the conditions of the case will warrant, will be found a proper selection. In every case, except for small plants, where engines are belted direct to generator, the vertical type of engine is recommended.

Royal Institution of Great Britain.—At the general monthly meeting, Monday, November 6, 1893, Sir James Crichton-Browne, M.D., LL.D., F.R.S. (Treasurer and Vice-President), in the chair, the special thanks of the members were returned to Lord Armstrong for his donation of £100 towards the fund for the promotion of experimental research at low temperatures.

THE CHLORIDE ELECTRICAL STORAGE BATTERY.*

BY HERBERT LLOYD, F.C.S.

The electrical accumulator which I will try to describe is known as the chloride cell. It is so called because the plates constituting the element are made up of tablets cast from fused chlorides of lead and zinc, held together by a frame or rim of antimonious lead. When these composite plates are cast, however, they are not capable of use in a storage battery. They do not contain material which is in any sense active material, nor material capable of becoming active in a secondary battery fluid. They are not capable of serving as oxygen plates, as they will not absorb oxygen, nor are they capable of use as hydrogen plates, as not only would their immersion in the dilute sulphuric acid of the storage battery result in contaminating the fluid with chloride of zinc, which would be fatal to its proper action as a storage battery fluid ; but the effect of the hydrogen liberated would be to form hydrochloric acid, with the chlorine of the chloride of lead, which hydrochloric acid would further contaminate the fluid and make it inoperative as a storage battery fluid. Moreover, these tablets are non-conductors of electricity. It is plain, therefore, that a plate consisting of tablets of chloride of lead and chloride of zinc is worthless as a storage battery plate, and cannot be used as such. Its chemical composition must first be radically changed to fit it for use either as an oxygen plate or a hydrogen plate. This chemical change is brought

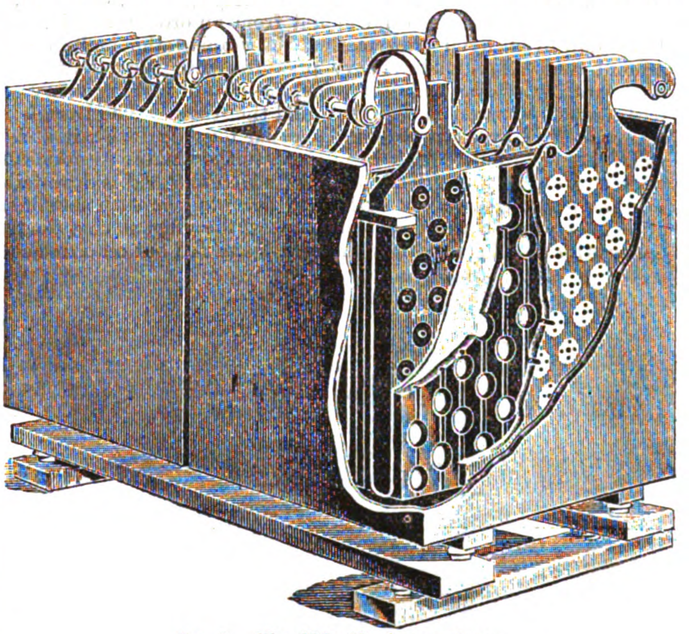

Fig. 1.—The Chloride Accumulator.

about by means of a bath of chloride of zinc or some equivalent substance, in which the plate of tablets is to be immersed in connection with a slab of metallic zinc. This arrangement is, in fact, a primary battery, in which the zinc acts as the positive element, while the tablets constitute the negative element. This operation may be performed with current produced by a dynamo ; but it is a very tedious and expensive process as compared with reduction by means of zinc.

The electro-chemical action in this combination results in withdrawing the chloride of zinc from the tablets by simple solution in the bath, and the withdrawal of the chlorine of the chloride of lead from the tablets, and fixing it in combination with the zinc with the formation of chloride of zinc. It may, therefore, be said that the chloride of lead tablets constitute material which is destined to become active by electrical disintegration, which is brought about when they are connected with the zinc plates in the bath of chloride of zinc. When this process of electrical disintegration is complete, and the chloride of zinc is washed out of the plate, a mass of crystallised metallic lead is left, which is suitable for immediate use in a storage battery, without the tedious forming process of Planté, and without the application of any active material or material about to become active by the processes of Brush and Faure.

To describe in detail the process used in the manufacture of this plate, as it is carried on commercially, I will begin with metallic lead. The first step in the production of chloride of lead is to bring the lead into such a state of subdivision as to make it readily soluble in nitric acid. A process which is satisfactory is to melt the pigs of lead in a suitable furnace, and when the lead is brought to a high state of fusion to convey it through a pipe into closed

* Abstract of a Paper read at the meeting of the Electrical Section of the Franklin Institute, September 26, 1893.

Digitized by Google

chamber, where it is delivered in a fine stream into a jet of dry steam, the result being that the lead is blown into a moderately fine powder, and falls on the floor of the chamber. This powder is then shovelled into earthenware baskets suspended in large tanks of dilute nitric acid. When the lead has gone into solution in the form of nitrate of lead, the clear nitrate of lead solution is run off into precipitating tanks, where, on the addition of hydrochloric acid the chloride of lead is thrown down in a fine white powder, nitric acid being set free. This nitric acid is returned to the dissolving pots to be used there again in bringing fresh lead into solution. The precipitated chloride is then washed by decantation and thoroughly dried.

The next step is to mix the chloride of lead so produced with the proper proportion of chloride of zinc, when both are melted together. I will show later on the direct effect produced by the chloride of zinc in the plate. The fused chlorides are next cast into tablets of any desired size or shape, and with a bevelled or V-shaped edge. These tablets are then placed in a second mould, called a framing mould, where they are placed at a fixed distance apart to allow the frame of antimonious lead to be cast around them. In this operation the result most desirable to obtain is to produce this framing lead in as dense a form as possible, so that, unlike the material destined to become active, it will not be attacked by the oxidising current when set up in a cell. The ordinary method of casting storage battery grids is, of course, to pour the molten lead into the mould from an ordinary ladle. We have improved upon this method by forcing the molten alloy around the tablets under heavy pressure, with the result of no only forming a dense metallic frame, but also of making a very perfect contact between the pastille and the frame. The pastille, at the same time, on account of its peculiar form, is dove-tailed, as it were, into the frame. This form obviates the trouble so noticeable with the ordinary red-lead plate, in which the grid is dove-tailed into the plug; that is, the surface of the plug on each side of the plate is of a larger area than the centre of the plug, so that the tendency is for the plug to split in the centre and fall out on either side.

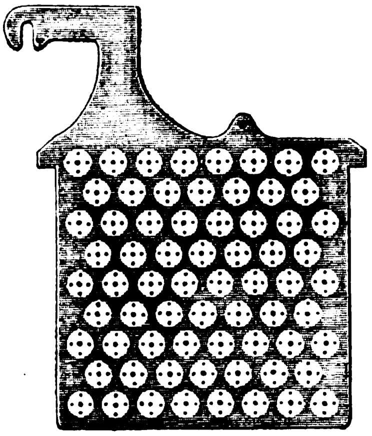

Fig. 2.—Chloride Accumulator Plate.

When the completed plate is taken from the framing mould it is placed in the reducing tank in connection with a plate of zinc, as described in the first instance. This reduction process extends over a period varying from 12 to 24 hours, according to circumstances. When reduction is complete, the plate is thoroughly washed in running water. In order to be sure that the very least trace of chlorine has been removed from the plate, all plates are set up as cathodes in a bath of dilute sulphuric acid, plain lead plates being used as permanent anodes in this tank, and a heavy current is passed through the plates for several hours. If the reduction has been incomplete the chlorine will make itself felt in this operation. Excepting through carelessness on the part of the workmen it is practically impossible for the plate to contain any chlorine at this stage.

When the plates are removed from the hydrogen bath they are next set up in forming tanks in connection with the plain lead permanent negatives, and here they are charged continuously for several weeks, or until the crystalline, spongy lead has been completely converted into peroxide of lead. The theoretical amount of current necessary to form a pound of peroxide of lead is about 200 ampere hours, and owing to the beautifully porous structure of the plate this figure holds out very well in practice; the plates will always be found thoroughly peroxidised after they have received a little over the theoretical quantity of current necessary. The positive plates after formation are then set up with the requisite number of negative plates (the active material of which is in a soft, spongy state as it came from the reducing tank), the lugs or terminals of the plates of each series being burned together with a hydrogen flame, after being insulated. The cells are then charged and discharged a few times until they give their proper capacity, when they are ready for shipment.

Chloride of zinc is used in this plate for two reasons. In the first place, it is impossible to cast plates of chloride of lead without it, as the casting on cooling falls to pieces, so the admixture of chloride of zinc is absolutely necessary on that account. In the next place, it will be readily seen that by the use of chloride of zinc it is possible to so control the density of the plate as to produce any porosity that may be desired, and as within certain limits the capacity of a plate is proportional to the porosity, this use of chloride of zinc is of vast importance. In the manufacture of the ordinary red lead or pasted plate, the density of the material depends mainly upon the energy which the boy uses in pushing the red lead into the grid, and consequently the plates are seldom or ever uniform. In the chloride cell, providing the materials are properly weighed and the mixture thoroughly stirred after fusion, the plates are essentially uniform, as the mixed chlorides become perfectly fluid and every plate cast is exactly like every other plate. It is never necessary to reject any plate for want of capacity. The mixed chlorides, on cooling, crystallise into a hard, stony substance of a peculiar crystalline nature. After reduction the metallic lead is left in the form of fine acicular crystals, running through the plate perpendicular to its surface, and the elimination of the chlorine and the chloride of zinc provides minute cell spaces around these crystals, so that an immense surface is offered for the absorption of oxygen in the forming process.

Having arrived at the proper amount of chloride of zinc to use, there is no danger of buckling or warping of the plates from undue expansion, as this expansion can be accurately provided for in the tablets.

The capacity of cells of this type is from five to six ampere hours per pound of plate. The capacity for weight could be materially increased, but at the loss of durability. At a discharge rate equal to one-half an ampere for each pound of plate, which is a higher rate than is recommended for any other lead element, this capacity of between five and six ampere hours per pound can be obtained. At this rate of discharge the efficiency of the cell will be very high, the loss in current being less than 10 per cent. and the watt-hour efficiency from 75 to 85 per cent. At the rate of one-half ampere per pound, over three-fourths of the capacity can be obtained above two volts. This is, in my opinion, a very desirable feature.

An examination of the complete element will show the special care that has been given to the insulation of the plates. It is well known that the liability of a storage battery to short-circuit has been one of the main causes of trouble. To overcome this, we envelop the positive plate in a piece of woven asbestos cloth. Between this positive so protected and the negative plate we place a perforated, grooved board of insulating material, the perforations in this board being made opposite the pieces of active material in both plates, leaving free circulation of the electrolyte between the plates, at the same time keeping the asbestos cloth pressed against the face of the positive plate, causing it to form a tight covering over the face of the active material, and while making the plate absolutely safe from short-circuit, it also adds very wonderfully to the life of the cell, since the peroxide is held in position where it can perform useful work instead of being deposited on the bottom of the cell. The channels in the board provide for the free circulation of the electrolyte, and also allow for the escape of the gases. In traction work this form of insulation is found very beneficial, as the cell is vastly more durable than anything that has been before produced, and at the same time there is no unnecessary liquid to be spilled over the car.

It may be of interest to state that the Company manufacturing this type of cell in France has supplied batteries for nearly two years to the North Paris Tramway Company, who operate two or three roads with battery cars, about 40 cars in all, I believe. I was on these cars about a year ago, and they certainly were doing good work. The cars are about 22ft. long, and have seating room for 54 passengers. The Paris factory has for some years turned out over five tons of plates a day. They equipped the Popp stations in Paris with these accumulators some three years ago, which have been in constant use ever since. There are 24 substations all charged in series, the lighting being done entirely from the batteries, there being two sets in each station, one being discharged, while the other one is charged. There are in the neighbourhood of 100,000 lamps run daily from these cells, the result obtained being very satisfactory, since, in addition to the benefit derived from the batteries as a store, they also act as transformers, as the batteries are charged in a 3,000-volt circuit, each station turning out current to its immediate vicinity at 110 volts. The plates in some of these cells weigh 100lb. each, the complete cell weighing over a ton, and discharging at a rate of from 1,000 to 2,000 amperes each. A company has recently been formed in England for manufacturing these cells, which has just completed works near Manchester capable of a very large output. That company is controlled by Messrs. Mather and Platt, and the business is to be managed by Dr. Hopkinson. Under such management there can be very little doubt about the success of the business.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 27, 1893.

The American Street Railway Convention.—The twelfth annual meeting of the American Street Railway Convention, recently convened at Milwaukee, was one of the most successful yet held. The principal Paper read was that of Mr. C. O. Mailloux, on the use of storage batteries as auxiliaries in power stations, in which it is shown that in many cases it will be profitable to add a battery plant. This subject has been much neglected in America, and Mr. Mailloux's Paper will perform a good office by bringing discussion to bear on it. Another Paper advocated the use of multiphase expansion engines for large plants. Direct connected power generators were strongly advocated, which is another indication of the disfavour with which belted plants are beginning to be viewed in the United States.

The Brooklyn Bridge.—The Brooklyn Bridge authorities are beginning to investigate the subject of electric traction, with a view to its adoption on the bridge, in which at present the cable system is used for running the cars. It is thought by some, however, that there is little likelihood of the electric system being adopted, on account of its expense, and less safety from accidents through collision.

The General Electric Company.—This Company has fared somewhat better in the Stock Market recently, its shares now standing at 49 (par, 100). There are many rumours of an entire reorganisation, and a still greater reduction in its salaried *employés*.

American Institute of Electrical Engineers.—Dr. Bedell has described a new method of instantaneous contact in the measurement of alternating currents, and some experiments on a Hedgehog transformer. The conclusion was favourable toward this type of transformer and toward using condensers to reduce the line current, which latter method is employed in the Stanley-Kelly two-phase system. The Paper of Mr. Pope considered the subject of local meetings of the Institute, which is now a subject under much discussion.

THE CITY COMMISSIONERS OF SEWERS.

Mr. H. H. BRIDGMAN (the Chairman) presided at the fortnightly meeting of the Commissioners at the Guildhall on Tuesday last.

Mr. GORDON moved the following resolution standing on the agenda paper in his name: "That it be referred to the Streets Committee to consider the question of appointing an inspector or inspectors under the Electric Lighting Acts."—Mr. McCARTHY having seconded the motion,—Mr. Deputy Cox pointed out that the gas light inspector, whose office he had always thought was a useless one, might be utilised for the purpose.—Mr. GORDON thought that would not be possible, because it was evident that the inspector must be a competent official. For instance, the Committee had recently received a complaint from a firm in the City stating that there were serious defects in their electrical arrangements, and asking that an inspector should be sent. He considered that the Commissioners should have had an inspector to send without delay, instead of which there was none.—The motion was then adopted unanimously.

Mr. JOHNSTON, in moving "That it is expedient that Crutched Friars be lighted by electricity, and it be referred to the Streets Committee to carry out," said in consequence of what was stated at the last Court to the effect that Crutched Friars was not included in the list of the main thoroughfares he had consulted the engineer, who had confirmed that opinion. But although it was not scheduled as one of the main thoroughfares, it was very necessary that a street which was so greatly used by all kinds of traffic should be thoroughly lighted, which was not the case at the present time.—Mr. C. T. HARRIS expressed a hope that the street in question would be lighted by arc lights. [Mr. JOHNSTON: "Oh! certainly."] He preferred also that some statement should be furnished to the Court on the question of cost. He was not sure that the electric light would prove the most effective means in so dark a thoroughfare where there were few shops to assist in lighting the street. The reason why London Bridge was not lighted by electricity was because the dark shadows thrown by the light and the absence of supplemental radiance from shops interfered with the traffic. He would prefer, therefore, and would move as an amendment, that the question should be referred to the Streets Committee to consider. With regard to the cost of lighting the eastern district of the City, he found it was nearly 20 per cent. in advance of that for the main thoroughfares of the City. In the eastern district there were 233 arc lights, which at £26 per annum, cost £6,058; adding to that the cost of maintaining disused gas lamps, about £450, the total would be £6,500. The previous cost of lighting by gas the whole (three districts) of the City with 1,730 lamps was £5,550. To light the district by electricity thus cost £1,000 in excess of the expenditure required to light the whole of the City by gas. And yet they were told that the cost of the new light would not be more than double that of the gas, while it was actually three and a-half times the cost in the eastern district.—Mr. JOHNSTON said he was prepared to accept Mr. Harris's suggestion. The motion was then adopted.

The report of the Streets Committee contained a copy of a communication from the City of London Electric Lighting Company on the subject of the laying of tubes for telephone purposes in the trenches with the electric lighting tubes. The Company, in reply, stated that except for purposes of their own the tubes were not being used for telephone purposes.

Mr. PANNELL called the attention of the solicitor to a communication which had been addressed to him (the speaker) on the subject of the National Telephone Company. The letter ran as follows:—"I desire to remind you of the impending consideration of the telephone communication which will be submitted to the House in all probability within a few days. You will remember that Mr. Arnold Morley claimed to have the right of signing the agreement with the National Telephone Company before laying the agreement on the table of the House. After a great deal of effort by various members of public bodies, he consented to lay it on the table before signing it. It is most important this agreement for 18 years should be examined very carefully, as it is almost certain to allow of encroachments on public rights, and for the purpose of taking action in regard to it the Association of Municipalities has appointed a Special Committee. I now beg to suggest that, in addition to taking an active part in the House, you should use your influence to induce the Commissioners of Sewers to appoint a committee to take what steps they may deem necessary, as it is all too certain that the agreement will contain provisions that will call for strenuous opposition." Mr. Pannell added that he would like to know why the subject had not been reported to the Commissioners, because otherwise the Court might have been placed in a very serious position, and he desired to move that the Streets Committee should work in accord with the representatives of the Association of Municipalities, and that the Committee should be empowered to do therein as they might be advised by their officers.—The SOLICITOR replied that it was understood that the agreement would be submitted to the judgment of the House, and that the Commissioners would have an opportunity of expressing an opinion upon it.—The CHAIRMAN said he understood also that the Remembrancer would obtain a copy of the agreement in question. Mr. Pannell's motion having been seconded, it was adopted, and the name of the mover was ordered to be added to the Committee.

The ENGINEER submitted an interesting report on the subject of the number of failures which had taken place during the past six months in connection with the electric light. The total number of arc lamps in use was, he reported, 475. The number of gas lamps disused, but maintained ready for lighting, was 1,219. The total number of failures of the electric light during the period in question was 301. The most serious failure was on May 7th, when 42 lamps were not lighted until nine o'clock. The explanation given by the Company was that the switch was defective. On June 17th 65 lamps went out for a considerable period, but the gas was not lighted. The explanation given by the Company was that there was negligence on the part of the stoker at Wool Quay. On July 27th 96 lamps went out, and the reason given was the breaking of a belt. The 475 arc lamps, at a cost of £26 per annum each, gave a sum of £12,350. The length of streets lighted was 13 miles. The fines for these defects would be deducted from the next account of the Company. The information regarding these failures was received from the police force, and the returns were sent to the Company's office and filed in his office.—On the motion of Mr. MALTHOUSE, it was resolved that this return should be printed and circulated.

LEGAL INTELLIGENCE.

Ives and Baker v. Willans.—The Liverpool Overhead Railway.

This action came before Mr. Justice Kekewich on Tuesday last. It was an application on behalf of the defendant to stay all proceedings in the action under the Arbitration Act, the matter being covered by the arbitration clause in the contract sought to be enforced.

Mr. Warmington, Q.C., M.P., and Mr. Bramwell Davis appeared for the defendant, and Mr. Renshaw, Q.C., and Mr. Peterson appeared for the plaintiffs.

Mr. WARMINGTON said that, except that the plaintiffs scattered charges of fraud against persons who certainly up to now held a high position in the commercial world, there was very little to answer. Mr. Willans entered into a contract, called the principal contract, for the construction of the Liverpool Overhead Railway. That was a very considerable work, and Mr. Willans entered into a series of sub-contracts for various parts of the work. Amongst these sub-contracts was one dated August 24, 1889, between the defendant and the plaintiffs. Clause 9 of that contract provided that all questions arising from that agreement should be settled by the engineers in the manner mentioned in the principal agreement. The clause in the principal agreement was to the effect that if any question, difference, or dispute should arise between the Company and the contractor the matter should be referred to the engineers, whose decision should be final, and that neither of the parties thereto should commence or prosecute an action. The plaintiffs issued their writ on July 1, 1893, claiming the sum of 3d. per ton for removing the decking, a declaration for specific performance, and for a declaration that the defendant was not entitled to charge a toll in respect of plaintiffs' bogies running over the swing bridge, and for an account between the plaintiff and defendant. The charge for removing the decking was some £83 odd, and although the plaintiff might be entitled to sue for that there could be no doubt from the documents that he was entitled to a stay under the Arbitration Act respecting the other matters. The defendant set out the arguments in his affidavit. The affidavit of the plaintiff Baker, he being the only plaintiff who had sworn an affidavit, stated that the plaintiffs objected to the gentlemen (the engineers) who were named in the contract, who, they said, were likely to be prejudiced against them. These gentlemen were Mr. Barry Fox and Mr. James H. Tracey, who were two of the best known engineers in the country. The plaintiff further said that he had suffered damage in respect of the non-execution of the defendant's contracts of some works which in some way were connected with the plaintiffs, and that this delay injured the plaintiffs in the performance of theirs. If that was so it was damage for which he could obtain the relief. There was also some point about production. If they were entitled to that the arbitrators would give them it.

Mr. Justice KEKEWICH: It is a question whether this is the tribunal or whether he should go to the engineers.

Mr. WARMINGTON: Precisely. With regard to the decking, he did not think he was entitled to restrain the plaintiffs, but in all other matters he submitted he was. All the authorities were in favour of his contention. The documents showed that all matters with the exception of the decking were covered by the arbitration clause, and he had to ask his lordship to grant the order asked.

Mr. RENSHAW submitted that defendant had taken a step in the proceedings, and was therefore debarred from making the present application. His clients were willing to have the matter referred to independent gentlemen, but they strongly objected to having matters in which they were so deeply interested referred to the engineers.

His LORDSHIP made an order under the Arbitration Act staying proceedings excepting the claim for decking and the claim for damages for delay, the plaintiffs to have liberty to amend their writ.

Upon the application of Mr. RENSHAW, each party was ordered to pay their own costs.

Pollard v. Rust.

This was an action tried on Monday last before Mr. Justice Cave without a jury, and brought by Mr. E. H. Pollard, a barrister, to recover damages for breach of an agreement dated May 19, 1885, or, alternatively, to recover the sum of £1,333. 6s. 8d., money alleged to have been received by the defendant for and on behalf of the plaintiff. In 1884 Mr. C. Langdon Davies obtained protection for an invention entitled "Improvements in Telephony," of which he was the inventor, and had had advanced to him by the defendant £2,000 for the purpose of perfecting his patents. On May 19, 1885, an agreement was entered into between Mr. Davies and the defendant, whereby the defendant was to advance to Mr. Davies a further sum of £2,000 upon the signing of the agreement, and a further sum of £6,000 under certain conditions embodied in the agreement; it was also provided that should a sale of the inventions be effected without the payment of the £6,000 then there should be paid to the defendant out of the moneys received as purchase-money the sum of £4,000, and after a like sum had been received by Mr. Davies he was to pay a bonus of £4,000 out of the next moneys received as purchase-money, but in the event of no sale being effected before December 31, 1885, then the defendant was to be paid the sum of £4,000, with a bonus of £2,000. By a memorandum of agreement made between the plaintiff and defendant, the plaintiff agreed to guarantee the repayment of £2,000 advanced by defendant to Mr. Davies, and the defendant agreed to pay the plaintiff two-thirds of all bonus he got in respect of the first £2,000 paid by him to Mr. Davies as soon as he received the same. On July 20, 1887, an agreement was entered into between Mr. Davies and the defendant, which recited that £2,000 bonus was due to the defendant, and it was agreed that the defendant should purchase from Mr. Davies certain patent rights, and that as to £2,000, part of the purchase-money, the same should be paid by the defendant releasing his right to the said bonus. The plaintiff now claimed two-thirds of the £2,000 under the agreement of May 19, 1885.

After hearing counsel for the parties,

Mr. JUSTICE CAVE, in giving judgment, said that the bonus in respect of £2,000 was £1,000, and two-thirds of that sum became due to plaintiff, which he was entitled to have paid to him when the money was actually received from Mr. Davies. Had it been received from Mr. Davies? He was of opinion that it had. The position was this. Mr. Davies had got the patent rights subject to repaying Mr. Rust the money, but plus the bonus. Mr. Rust had put it out of their power to say whether the £2,000 would have been received, so the Court must consider that it had been received. There had been what was equivalent to payment of the whole bonus payable. The plaintiff was therefore entitled to judgment for £666. 13s. 4d.

Wilkinson v. Medical Battery Company (Limited).

This action came before Mr. Justice North, in the Chancery Division of the High Court of Justice, on Saturday, as a short cause, the points on which judgment was asked having been agreed upon between plaintiff and defendants. The action was brought by the plaintiff on behalf of herself and all other holders of the defendant Company's debentures for the purpose of enforcing their security, as the debentures expressed that the principal moneys which they acknowledged to be advanced became payable immediately on a meeting being called to consider a resolution to wind up the Company. The meeting was called for, and held on, Friday last, when it was resolved to wind up voluntarily.

Mr. Tanner appeared for the plaintiffs, Mr. George Henderson for the Company.

Mr. JUSTICE NORTH gave judgment as asked, declaring that the debentures were a first charge on the assets of the Company, and directing the usual accounts and inquiries.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES' DIRECTORY AND HANDBOOK" contains over 1,000 pages, several new and handy features having been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

The 1894 Edition is in preparation, and will be published in January next. New names, alterations of addresses, &c., are received at any time, but the Directory blanks and circulars are not sent out until later in the year, in order that the most recent, and consequently the *correct*, **addresses** *only* **shall appear in the book. Full printed particulars can be obtained, post free, from "The Publisher,"** *Electrician* **Office.**

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, which has a special interest at the present time, is now ready, and will be forwarded on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus can be obtained on application to the Publisher.

TENDERS INVITED.—The Corporation of Dublin invite tenders for the extension of the buildings and the supply and erection of additional plant at their central station in Fleet-street. Plans may be seen, and specifications and forms of tender obtained, at the offices of Mr. Spencer Harty, the city surveyor, at the City Hall, and tenders are to be forwarded to Mr. H. Campbell, the town clerk, at the City Hall, by 5 p.m. on December 14th. Further particulars appear in our advertisement columns.

——— With regard to the tenders invited for the Newport plant, these tenders can be for portions of the plant, and should be sent in by the 20th inst.

——— The Directors of the Waterhouse Electrical Manufacturing Company (Limited) invite tenders for the supply of electric arc lamp-posts. Specifications, &c., can be obtained on application to the Secretary of the Company, and tenders must be sent in not later than November 18th.

——— The Midland Railway Company invite tenders for a variety of stores, including castings, copper and brass tubes, brass engine fittings, telegraph instruments, stay-rods, belts, &c., telegraph and signal wires, English timber, fog signals, indiarubber brake pipe, washers, &c., all to the Company's patterns. Tenders have to be in not later than 9 a.m. on the 16th inst.

——— Tenders are invited for the establishment of a central electric lighting station, with a capacity of 4,000 incandescent lamps at Davos-Platz, Zürich. Water power is to be utilised. Tenders must reach the Municipal Authorities by December 20th.

Digitized by Google

SALE BY AUCTION.—Mr. J. C. Stevens announces in our advertisement columns that he will include in his sale at his rooms, King-street, Covent Garden, on Friday next, the 17th inst., the stock and plant of an electrical engineer, comprising dynamos, electroliers, electric light fittings, lathes, tools, &c.

AMALGAMATION OF MESSRS. ELLIOTT BROS. AND MESSRS. THEILER AND SONS.—We understand that the business of Messrs. Theiler and Sons, which has for some time past been managed by Mr. G. K. B. Elphinstone, is being amalgamated with that of Messrs. Elliott Bros. Messrs. Elliott Bros. were established in the year 1800, and Messrs. Theiler and Sons in 1857. A considerable trade in telegraphic and other instruments will thus be added to Messrs. Elliott Bros.' already extensive business. We understand that Mr. Elphinstone is joining Messrs. Elliott Bros. as a partner.

APPOINTMENT.—Mr. Francis Teague has been appointed resident manager of the Scottish House-to-House Electricity Company's new generating station at Coatbridge.

LIQUIDATIONS.—A general meeting of the members of the Pioneer Telephone Company (Limited) is to be held at 1 and 2, Great Winchester-street, E.C., on December 4th, at 3 p.m., for the purpose of receiving the liquidators' account of the winding-up.

——— Messrs. Max Binswanger, Edmond Kahn, and William Watts have been appointed a Committee of Inspection to act with the Official Liquidator in the matter of the Art Workshops, Limited (in liquidation).

——— The petition for the compulsory winding up of the Ipswich Electricity Supply Company (Limited) came before Mr. Justice Vaughan Williams on Wednesday, when a decision was postponed in order that a meeting might be held to endeavour to settle the dispute that had arisen as to who was entitled to use the name of the Company. It appeared that Mr. Shorrocks, the petitioner, held 50 shares out of 58, and did not wish the receiver to sell the property under a certain contract.

BANKRUPTCY.—An application was made at the London Bankruptcy Court on Thursday for an order of discharge on behalf of Henry Bury, formerly carrying on business as electrical engineer in Manchester; but after hearing evidence in support of the application, the Registrar suspended the bankrupt's discharge for two years.

MR. L. P. CASELLA.—Mr. Casella has been appointed agent for the sale of automatic recording instruments (*système* Richard), and is preparing a complete illustrated catalogue.

PERSONAL.—Mr. W. F. Taylor, consulting electrical engineer, of Boswell-court, Croydon, was elected to the County Council of the Borough of Croydon on the 1st inst.

O.-E. METERS.—Mr. Joseph Edmondson has received orders for two 750-ampere O.-E. meters, to be used for registering the total output from the whole of the electric lighting station at Hull. These meters are to be coupled to the two outside conductors of the three-wire system.

LUBRICATORS.—Messrs. O. Berend and Co. forward us their latest revised list of grease and oil lubricators, syringes, oil filters, &c. The list is fully illustrated with a variety of tools and appliances sold by the firm.

ELECTRIC COOKING AND HEATING.—The General Electric Company have sent us their catalogue, Section H, with full illustrations and descriptions of their kettles, steamers, ovens, grillers, laundry irons, and other utensils and apparatus. The current required, and the time of heating, are given, together with estimates of the cost of use. The appliances are all marked with the necessary current in amperes. The wire resistances used are embedded in an insulating cement. An efficiency of nearly 90 per cent. is claimed.

SWITCHBOARDS.—We have received from Messrs. Mavor and Coulson, of Glasgow, a photograph of a set of cast-iron switchboards. The centre portion consists of three separate cast-iron panels, each panel carrying a 700-ampere fuse, switch and ampere gauge, also a regulating switch for dynamo shunt resistance. The panels are mounted in an angle iron frame and surrounded by a polished oak moulding. The distributing boards mounted to the right and left of the dynamo switchboard consist of 24 100-ampere fuses and switches. These switches are mounted in groups of three in an angle iron frame, and surrounded with polished wood moulding. Any number of additional panels may be added as required. The cast-iron panels on which the switches are mounted have planing strips upon which the contact blocks, &c., are fitted, the insulation being effected by mica. The surface of the cast-iron is finished with a smooth black enamel. These switchboards, which are for a concentric installation, are provided with omnibus negative bars, carrying cable sockets, by means of which the negative connection is effected.

EXTENSION PLATFORM LADDERS.—Messrs. Heathman and Co. have recently supplied a number of their patent extension platform ladders for use in tending the arc lamp-posts at Liverpool-street and Bishopsgate-street Railway Stations. These posts are 21ft. high, and the ladders (which will pass through a doorway 6ft. 6in. high) have a spacious platform, with guard rail, enabling the lamp trimmer to work in safety. The same firm have recently supplied ladders to reach to the top of the 40ft. posts at the Battersea New Town Hall, and have in hand street ladders built on high wheels for the Kingston-on-Thames installation, where the lamps are 26ft. high.

STEAM-POWER.—We have received from the New York Safety Steam Power Company a well-printed catalogue illustrating and describing various engines and boilers manufactured by the Company. Included in the list are several vertical high-speed engines specially designed for electric lighting, and a number of tables and prices of the machines are given.

RATING OF MACHINERY.—The Machinery Users' Association are advised that the time is now ripe for obtaining a legal decision which would probably be entirely favourable to their contention as to the interpretation of the Tyne boiler judgment. Two recent cases have resulted in decisions favourable to the position taken up by the Association.

MESSRS. PYKE, HARRIS AND CO. (LIMITED).—With reference to the law-suit, Newman *v.* Hall, this Company ask us to state that neither Mr. L. S. M. Pyke nor Mr. Edward S. Harris have any knowledge of, or connection with, the Mr. Pyke or Mr. Harris therein mentioned.

TELEPHONE ATHLETIC ASSOCIATION.—This Association gave a smoking concert at the "Haunch of Venison," Bell-yard, Fleet-street, E.C., on Friday last, at which Mr. Dane Sinclair, engineer-in-chief to the National Telephone Company, presided. An enjoyable evening was spent.

CHICHESTER.—Mr. Councillor Prior has submitted a report to the sub-committee of the Lighting Committee of the Town Council, on the probable cost of lighting the city by electricity. He estimates the initial cost of lighting the principal streets would be £12,500 to £14,000, and the annual outlay (including repayment of loan and interest) £2,791. The probable revenue from private consumers would be £3,000, and as there would be a saving over gas for public lighting of £300, the works would earn an annual surplus revenue over expenses of £500.

DUBLIN.—On Thursday last Mr. C. P. Cotton, Local Government Board Inspector, held an inquiry at the City Hall in reference to an application by the Corporation for a loan of £24,400 for the purpose of extending the electric lighting of the city. In supporting the application, Mr. Harty, the borough surveyor, said that the present works, which cost £37,000, had proved so successful, and there had been such a large demand on the part of the citizens to obtain the advantage of the electric light in areas not now served by the present supply, that the present application had become necessary.

EAST HAM.—The Local Board have recently opened an infectious diseases hospital on their sewage works, and have lighted it by electricity, the motive-power for generating which is supplied by the pumps.

ELECTRIC LIGHTING FOR CARRIAGES.—Messrs. Slatter, of Long-acre, the builders of the state carriage for the Lord Mayor of London, have made a special study of carriage lighting by electricity, and their latest form of lamp is fitted to this splendid coach. It is placed inside, in the centre of the roof. At the back of the lamps is a domed enamelled reflector. Experiment having shown that when the platinum wires become hot they droop downwards, in order to obviate this drawback a little glass stilt is now added, which is not to be seen in the ordinary incandescent lamp, as in order to economise space the lamps are not hung vertically in the reflector, but lie horizontally. In the first attempts to light carriages in this manner the vibration of the travelling was apt to jar the lamps, often causing a breakdown, and steel springs were not found sufficient to prevent this. The plan now adopted is to suspend the complete lamp in a sheet of rubber, which is attached to the interior of the carriage, and neutralises the vibration. The accumulators are carried in the boot, under the coachman's seat, and are easily accessible. Mr. James Pitkin's carriage accumulator has been found in actual use to supply current to keep a lamp alight for eighteen hours, which is sufficient to last the owner of a brougham for three weeks to two months.

GLASGOW.—At the last meeting of the Town Council the Gas and Electric Lighting Committee reported that Mr. Arnot, electrical engineer, had submitted the statement of cost which he had been instructed to prepare regarding the lighting of the tramway cars by electricity. The Committee were of opinion that it would be more convenient and expedient to make arrangements for charging the accumulators required for lighting the cars at one or more of the car depots now being erected by the Corporation instead of having them charged at the central electric lighting station. This course was approved by the Town Council. The Council also resolved that the Corporation Art Galleries should be lighted by electricity.

Digitized by Google

KENDAL.—The Town Council at their last meeting had under consideration the advisability of applying for a Provisional Order empowering them to supply electricity, but it was decided to defer the matter for the present, as the Corporation were already proposing to acquire the local gas and water works.

LECTURES.—Mr. W. W. Haldane Gee is giving a course of six weekly lectures upon "Fire Risks of Electric Lighting" to the members of the Municipal School of Electrical Engineering, at Winkworth-street, Manchester.

——— Dr. Fleming delivered his Gilchrist lecture on "Magnets and Electric Currents" at Bournemouth, on Friday evening before a large and appreciative audience.

LONDONDERRY.—The Corporation have given the contract for the supply of lamp pillars for street electric lighting to Messrs. Alexander Brown and Son, of Derry, at £9 each.

TUNBRIDGE.—Mr. Arnold Taylor, Local Government Board Inspector, held an inquiry at the Town Hall, on Thursday last, in regard to the application made by the Corporation for a loan of £13,000 for the purpose of lighting the borough by electricity.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS.

Western and Brazilian Telegraph Company (Limited).

The following is the Report of the Directors to be presented at the twenty-sixth ordinary general meeting of the Company, to be held at Winchester House, E.C., on Thursday, the 16th inst., at noon :—

The total earnings for the half-year ended June 30, 1893, amount to £79,353. 10s. 4d., as against £84,021. 16s. 9d., a decrease of £4,648. 6s. 5d., compared with the half-year to June 30, 1892. The working expenses amount to £43,424. 1s. 3d., as against £39,140. 16s. 8d., an increase of £4,283. 4s. 7d.

The above comparisons are made, as usual, with the corresponding period of the preceding year, but the expenses for the two periods necessarily differ because of the extra staff and arrangements required to work efficiently the duplicated and duplexed line, completed in 1892. At the meetings held in November, 1892, and May last, the Chairman pointed out that the duplicated and duplexed Cables would have to be worked to the best advantage to enable the Company to hold its own with the traffic. The expenses, therefore, for the past half-year under Abstract "A" should be compared with those of the half-year ending December, 1892, when the additional circuits were being manned and worked, and it will be seen that as regards the main items, notably "salaries in Brazil," no real increase occurs, the amount under this head being almost identical. Following upon the measures taken the volume of traffic has increased 12½ per cent., which is satisfactory. Notwithstanding, however, the substantial increase in the number of words carried, the revenue derived owing to various causes, unavoidable alterations in tariff, changes in locality of traffic, and so on, shows the reduction already pointed out in paragraph 2.

The shareholders were also informed as to the arrangements for the ultimate employment of one ship instead of two, as heretofore. The half-year under review was a transition period, during which the two former vessels and the new substitute were necessarily all three in commission, two on the coast and for a time coming home, and the new ship on her way out. The "Norseman" No. 1 and the "Viking" have now been laid up pending sale or employment, and the Directors are glad to say that the policy of the Board has so far been successful, both as to the value of the new steamer in the matter of speed during the present critical time in Brazil (where she has just rendered special and important service) and as to future expenses. The economy insured under this head will become apparent in the accounts for the current half-year.

Including the amount brought forward from 1892 (£2,829. 15s. 6d.), the balance to the credit of the revenue account is £38,779. 4s. 7d., from which has to be deducted £12,093 for debenture interest, and £7,007 for the debenture redemption fund, leaving £19,679. 4s. 7d., of which £12,000 has been placed to the reserve fund. This leaves £7,679. 4s. 7d. to be carried forward.

The shareholders are aware of the exceptional state of affairs in Brazil, and the great uncertainty as to what the outcome may be. Under these circumstances the Board are unable to recommend a dividend at this time. With the restoration of tranquility, and an adequate increase in exchange consequent upon it, coupled with the improvements effected in the Company's arrangements, the financial position would be again satisfactory.

The Directors have to notify that the conversion of Ordinary shares into Preferred Ordinary and Deferred Ordinary shares (after January 1, 1894) will be suspended.

West India and Panama Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended June 30th, to be submitted to the thirty-third ordinary general meeting, to be held at Winchester House, E.C., on Wednesday, the 15th inst., at noon :—

The amount to credit of revenue for the six months ended June 30th is £46,687. 4s. 3d. against £44,148. 17s. 7d. for the corresponding half-year of 1892, and the expenses for the same period have been £24,794. 6s. 11d. against £28,589. 6s. 4d., leaving a balance of £21,892. 17s. 4d., which, with £1,430. 3s. brought from last account, makes a total of £23,323. 0s. 4d. Of this sum the Directors have placed £3,000 to reserve, leaving an available balance of £20,323. 0s. 4d., with which it is proposed to deal as follows :—

	£	s.	d.
First Preference Shares—			
Dividend, six months to June 30th, 6s. per share	£10,368	18	0
Second Preference Shares—			
Dividend, six months to June 30th, 6s. per share	1,400	14	0
Ordinary Shares—			
1s. per share (free of income-tax)	4,416	1	0
Balance to current half-year's account..............	4,137	7	4

The traffic receipts for the six months show an increase of £4,170. 13s. 4d. as compared with the corresponding period, this increase being largely due to an interruption of the French Company's cable to Hayti, which lasted about seven weeks, and diverted traffic to this Company's line. It will be remembered that the traffic receipts for the first six months of the last year showed a decrease of £3,762, attributable to the reductions in tariff made the year before. If the exceptional revenue derived from the interruption above referred to is left out of account, the traffic proper of this

Digitized by Google

Company's system shows a decrease of £2,391, in comparison with the traffic prior to the reduction made in 1891. Since the close of the half-year the Directors regret to have to report a further falling off of 15 per cent. in the estimated traffics up to date in comparison with the corresponding period of 1892.

The expenses of repairs to cables amounted to £10,520. 18s. 11d., being £12,358. 1s. 11d. less than those for the corresponding period. This decrease is due to fewer repairs, and to the smaller quantity of cable used.

The Company's repairing steamer "Duchess of Marlborough" has been brought home to be surveyed, in accordance with Lloyd's requirements. She has, after the completion of certain repairs, passed her No. 2 survey, and is now in London ready to be commissioned when required.

The Directors have to report, with much sorrow, the death of another member of the Board that was elected by the shareholders in 1874. Mr. Henry Weaver, whose name has been prominently connected with the telegraphic service of the country almost from its inception, died on September 20th last. His loss is deeply regretted by his colleagues. Under the powers given to them by the Articles of Association they have elected Mr. Gerald W. Balfour, M.P., to fill the vacancy thus created.

The Directors desiring to recognise the long and faithful services of some of the *employés* and to strengthen the good relations that exist between the Company and its staff, propose to follow what has become a very general practice, and to offer to bear one-half the expense of life or endowment insurances for some of those who have been in the Company's service a certain number of years. They trust that this measure will meet with the approval of the shareholders.

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, *pages* 320-348, *&c., &c.*]

ADVANCE BOILER COMPANY (LIMITED).—This Company was registered on October 31st, with a capital of £100,000, in £5 shares, to carry on the business of boiler makers, iron and brass founders, and mechanical engineers.

WILLIAM BANKS AND CO. (LIMITED).—This Company was registered on November 2nd, with a capital of £4,000, in £5 shares, to enter into an agreement with Mrs. Sarah J. Banks, of Bolton, for the acquisition of the business carried on by her at Bolton under the style or firm of "William Banks and Co.," and to carry on the business of electrical and mechanical engineers, opticians, manufacturers and vendors of mechanical, electrical, optical, photographic, and scientific apparatus and appliances, tool makers, metal workers, machinists, smiths, &c.

PIONEER ELECTRIC CARRIAGE COMPANY (LIMITED).—The statutory returns of this Company, made up to August 7th, was filed on August 10th. The capital is £20,000, divided into 400 shares of £50 each, and 36 of these have been subscribed for and allotted. Upon each of these a call of £10 has been made, resulting in the payment of £340, and leaving £20 in arrears.

RAINBOW ENGINEERING COMPANY (LIMITED).—The statutory return of this Company, made up to September 21, 1893, was recently filed. Out of a nominal capital of £20,000, in shares of £5 each, 1,776 shares have been taken up, of which 1,500 were issued as fully paid to Charles H. Bosher, of Thornton Heath, in consideration for certain patents and the business of mechanical and electrical engineers, electricians, &c., carried on by him at Westminster, under the style of Rainbow Engineering Company. Upon the remaining 276 shares a call of £1 per share has been made, resulting in the payment of £234, leaving £42 in arrears.

SPERRYN, McDONALD AND CO. (LIMITED).—Although this concern was registered in August, 1892, no registered office, returns or other information has been filed, and the officials have sent the usual warning notices, to which no reply has been sent. The Company will, therefore, be struck off the register unless an explanation be given.

TAYLOR AND TUCKER ART METAL COMPANY (LIMITED).—The usual return of this Company was filed on October 17th, when the full amount had been called and paid on 4,400 £1 shares, the remaining 600 being unissued.

VEALE AND CO. (LIMITED).—The first annual return of this Company, made up to September 29th, has been filed. 4,904 shares, out of a total of 10,000 £1 shares, have been subscribed for. Of these, 3,839 were issued as fully paid to John E. Veale, of St. Austell (Cornwall), and the remaining 1,065 have had the full amount called and paid on them. Messrs. Crompton hold 2,000 shares.

NEW BRANCH TELEGRAPH OFFICES.—The Direct Spanish Telegraph Company and the Eastern Telegraph Company announce that they have opened branch Telegraph Offices in the Foreign Auction Hall, Covent Garden Market, London, W.C., for the exchange of telegrams with Spain, the Azores, and the Companies' general systems of submarine telegraphs.

CITY NOTES, &c.

ALLDAYS AND ONIONS (LIMITED).—The report to June 30th shows a net profit of £11,544. 15s. 11d., to which is added the sum of £105. 17s. 5d. brought from the last account, making together £11,650. 13s. 4d. The Directors recommend a dividend of 10 per cent. on the Ordinary shares. It is proposed to issue 5,000 additional Ordinary shares.

CHATHAM, ROCHESTER, AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—A meeting of the shareholders was held on Wednesday week, when it was decided to issue £12,000 in debentures, £4,000 only to be taken up before another meeting of shareholders is called.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended November 5th were £871, as against £891 for the corresponding period of last year, being a decrease of £20. The total receipts for the half-year amount to £14,637, against £14,400 in the corresponding period of 1892, being an increase of £237.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The gross receipts for the month of October were £2,121, as compared with £2,307 for the corresponding period of last year.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for October amounted to £23,200 and from January 1st to October 31st to £226,800. In the corresponding months of 1891 and 1892 the amounts were £237,800 and £223,600 respectively.

MEDICAL BATTERY COMPANY (LIMITED).—A meeting of the creditors of this Company was held on Tuesday last at the offices in Oxford-street, London, to discuss the position of the undertaking, at which Mr. C. B. Harness presided. He said he was sorry to have to meet the creditors under existing circumstances, but he thought, as a preliminary, that it would be best if the Press were not allowed to be present. The Chairman's resolution to this effect was, however, immediately negatived. The Chairman alluded to the attacks made upon the Institution and himself by "a small body of persons." These attacks had caused a considerable damage to the Company, from which it was recovering, when the further attack by the *Pall Mall Gazette* was made. The result of the attack was that a writ was issued against the Company, and the debenture-holders had taken possession of the Company. The shareholders (of whom there were 28) had decided to put the Company into voluntary liquidation, with Mr. Davis as liquidator. In the meanwhile Mr. T. B. Browne (advertisement contractor, and creditor for about £1,000) had presented a petition for compulsory winding up, and the business was now being conducted under the order of the Court of Chancery. The business had been a rich one from the beginning. The liabilities were estimated at from £14,000 to £20,000, and the assets, as a going concern, were valued (he did not say by whom) at £60,000 or £70,000. As a dead concern it was comparatively valueless. They had got a princely business together, which had been pulled down by a "few dissatisfied persons." The only fault that was found with him was that he was not a qualified electrician; but he had never represented himself as such. The debentures only amounted to £8,000, and the other liabilities to something like £14,000. Their turnover had amounted to £16,000 or £17,000 a year, out of which there was a large profit. He believed the business had been injured 75 per cent. by the recent attacks. The action against the *Pall Mall Gazette* [to which reference was made in our last issue] would be fought to the death, and he had every reason to believe that he would get substantial damages. He defied the proprietors of the paper to prove a single statement they had made. In reply to a creditor, the Chairman said that if they offered him the position of Managing Director (which he had so recently resigned) under the suggested voluntary liquidation, he should take it without any remuneration whatever. He had lost a great amount of money over the transaction, and he intended to have it back again. The Solicitor to the Company said Mr. Harness had brought his action for libel against the *Pall Mall Gazette*, and if he succeeded there was no doubt the creditors would be paid in full, because the business of the Company would rise, Phœnix-like, from the ashes (loud laughter). Ultimately a resolution was moved, authorising the winding-up to be conducted under the supervision of the Court, and not compulsorily, and another that a committee of six creditors should be appointed, and obtain an expert to advise them. Several other amendments were also moved, and the Chairman appealed to the meeting to conduct the proceedings in an orderly manner, in the midst of which a creditor moved that the Company be wound up compulsorily. The Chairman pointed out that all he wished to do was to prevent the assets of the business from being destroyed by "a few interested persons," and the proposal for the compulsory winding-up was put to the meeting and lost by a large majority. The motion for winding-up under the supervision of the Court, and not compulsorily, was declared carried. Several creditors declared that the Chairman had not acted fairly; but he strongly defended his action, claiming that his only object was to act fairly by all concerned. It was then moved that a committee of six be appointed to represent the creditors at the Court; but the Solicitor pointed out the difficulty of getting six representatives of the creditors prepared to stay at the offices of the Company until midnight to decide upon their action. After further discussion the Chairman declared the last resolution lost; but a count was insisted upon, and it was found that the motion had been carried. [On Wednesday, in the Chancery Division, Mr. Justice Williams ordered that Mr. T. B. Browne's petition should stand over for the production of evidence as to whether or no creditors would be prejudiced by the voluntary liquidation. Mr. Cornelius Bennett Harness was arrested on Wednesday morning at Potter's Bar, near Barnet, and charged, with others, at Marlborough-street Police Court, on four counts, with false pretences and conspiracy to defraud. Prisoners were remanded on bail for a week.]

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 809.—Vol. XXXII. FRIDAY, NOVEMBER 17, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

As we only received a copy of Prof. Forbes' Paper on "The Electrical Transmission of Power from Niagara Falls" in the course of yesterday (Thursday), we can only print a portion of it this week. The chief point of interest appears to be the remarkably low frequency which has been chosen. In a later portion of the Paper Prof. Forbes relates that Mr. Brush once said to him in discussing this matter, "Really, your best plan would be to lower the frequency so much that you get a direct current." The advantage of low frequency for starting up is obvious, but the use of this expedient to improve the efficiency of the motors seems to be a confession of weakness in design. All sorts of other excuses can be brought forward, as is done by steam-engine builders who cannot run their engines fast without knocking and vibration, and demonstrate that, entropy being a function of the piston speed, the number of revolutions given in their catalogues is the best possible. Some further information about the Niagara plant will be found in our "Notes."

Up to the present, the expiry of the lamp patent offers many promises of high efficiency and one guarantee, but no novelties. Central station engineers are looking forward to the use of economical lamps for basements, passages, &c., where gas is often used, although electric light is used elsewhere. Such lighting would help to swell the day load. But hitherto, many consumers, aware that the all-day use of glow lamps in kitchens, sculleries, &c., would cost as much if not more than the whole of the ordinary domestic lighting, have allowed gas to remain in these places. Taking an 8-c.p. lamp at 2·5 watts per candle, used for 300 days in the year for 14 hours a day, the annual cost would be about £2. 19s. 6d., allowing the lamps at 1s. 6d., and current at 6d. per unit. But for stairs and passages, 4-c.p. lamps might often be used, if they could be obtained. We expected to see four or five candle lamps offered for sale, but have not yet come across any. There should, however, be no difficulty in making 4-c.p. 50-volt lamps. For passages and stairs these could be wired in series without any difficulty, unless from Insurance Offices, who have some times made obscure objections. Two 4-c.p. lamps would consume the same amount of energy as in the former case, costing £2. 2s.; and another 17s. 6d. must be added for renewals, making £3. 17s. for the two, or £1. 18s. 6d. each per annum. For passages and stairs in the upper part of a house light is wanted, say, from dusk till 11 p.m., that is, about 1,800 hours. A 4-c.p. lamp would then cost only about 16s. 6d. per annum.

Had we known that the loud-speaking telephone to which we alluded a fortnight ago was being made by Messrs. Muirhead and Co., and was to be seen at their showroom at Princes Street, S.W., we should not, of course, have commented on it without trying it. Though we are unable to trace the source of the information on which we based our remarks, we have but little doubt that the Graham Loud-Talking Telephone is the one of which we had heard. The fact that it is made by Messrs. Muirhead and Co. is in the first place a sufficient guarantee of excellence, and that it is the invention of Mr. Graham is a further promise of practical value. The proof, however, is in the use, and we can only say that having had an opportunity of testing the apparatus it equals any loud-speaking telephone that we have tried, and surpasses all but an instrument in the possession of the late L. J. Crossley, of Halifax, Yorks. At present the instrument is adapted only for short lines, without induction coils, but a receiver for use on exchange circuits is occupying Mr. Graham's careful attention. No bell is needed, for the caller need only speak into the transmitter in his ordinary tone, and he can be heard many feet away from the receiver at the other end. The voice is all but natural, and is entirely free from buzzing. A resonant trumpet is fixed in front of the receiver, and the voice is not more modified than if the speaker were actually speaking through the trumpet.

The question naturally arises, How is it done? The transmitter is an ingenious modification of the Hunnings, and presents nothing fresh in principle, but is only remarkable for excellent workmanship in details connected with the prevention of clogging of the powder. The inside of the receiver is rather a surprise, for it appears to be nothing whatever but a rather large Gower. The magnet is, of course, strong, and the coils are of very low resistance. The secret seems to lie in the careful design and proportion of parts. These are almost as indistinguishable by mere inspection as the design of an armature of a dynamo. An interesting feature of the apparatus is a commutator, by which any room in a building can communicate direct to any other room, without possibility of over-hearing or cross-talk.

The recent report of the engineer to the City Commissioners of Sewers in regard to the number of failures of the arc lighting in the City needs a word or two of explanation.

Digitized by Google

In our last issue we gave an account of the report, in which it will be found that during the past six months there have been 301 failures of light; and many of these were but for a minute or two. It is interesting to know that out of the 787,245 lamp-hours of possible running only 370 lamp-hours were lost.

A CORRESPONDENT of *The Times* has recently made a valuable suggestion which, it is to be hoped, will receive all the attention it deserves from the authorities in our London and other city hospitals. He suggests that all the hospitals in each town or city should be connected up on a special telephone circuit, just as it is intended to connect lighthouses and lightships. The importance of such a step is great, and the benefits to be derived from it are very numerous. At the present time each hospital is a detached and insulated institution, the staff of which is generally in perfect ignorance of the number of surgical beds or medical beds which are vacant in the neighbouring institutions. It is not an uncommon thing for a patient, often in a critical condition, to be carted round from Bart.'s to Guy's, St. Thomas's, Westminster, and perhaps the London or St. George's as well, finally being deposited, *pro tem.*, in some infirmary or taken home again. Medical men in one suburb often require to communicate with a hospital in a remote suburb: to telegraph is to lead to waste of time, and to ambiguities of all kinds; to cab it takes up time and money; to attempt to telephone is to find that the hospital, in many cases, is not even on the public telephone circuit. A private telephone circuit between all the hospitals, and a wire from each to the public exchange would greatly add to the harmonious integration of these institutions, and would increase their utility.

A Paradox.—A "dry" cell, says the *Electrical World*, is so called, because from its very nature it is always "wet," in order to distinguish it from the "wet" cells, which, if not attended to, may become "dry."

Cable Interruptions:

	Date of Interruptions.
Cayenne-Paramaribo	October 25th, 1893.
Perim-Obock	November 10th, 1893.

Royal Institution.—The annual Christmas course of lectures for children will this year be delivered by Prof. Dewar, his subject being "Air: Gaseous and Liquid." The first of the course will be delivered on Thursday, December 28th.

Compensation for Hysteresis.—We have received, too late for insertion this week, a communication from M. Abdank-Abakanowicz, commenting on Mr. Vignoles' article on this subject, together with some interesting diagrams, which we hope to reproduce in our next issue.

Lady Engineers.—Miss Bertha Lamme, of Springfield, Ohio, who recently received the American degree of electrical engineer at the Ohio State University, is said to be the first woman in the world to obtain this distinction. Miss Lamme has already accepted a position with the Westinghouse Company at Pittsburg.

Lecture.—A popular lecture on "The Supply and Measurement of Electricity" was delivered on Thursday, November 9th, by Prof. S. P. Thompson, F.R.S., at the Victoria Rooms, Bristol. Bristol people have been a long time waiting for the supply, and are growing impatient; we hope they will find the measurement satisfactory when it comes.

Manchester.—A short circuit occurred, at eight o'clock yesterday morning, on the mains of the Manchester electric power supply, which are laid on the five-wire system. An explosion ensued, resulting in the cover of one of the junction boxes being blown into the air. It was found necessary to switch off the current from the section on which the accident took place.

Personal.—In the list of honours conferred by H.M. the King of Portugal given in our issue of the 3rd inst. the following should have been included:—To be Chevalier of the Military Order of S. Bento de Aviz, John Seymour, Commander of the s.s. "Seine"; to be Chevalier of the Ancient Most Noble and Enlightened Order of S. Thiago, for scientific, literary and artistic merit, Francis Robert Lucas, Engineer-in-Chief of the Expedition on board the "Seine."

The New Atlantic Cable for the Commercial Company.—Messrs. Siemens Bros. and Co. (Limited) have received instructions from the Commercial Cable Company to proceed forthwith with the manufacture of a new cable to be laid between Ireland and Nova Scotia. This cable, which will be over 2,000 miles in length, is to be built to a specification ensuring higher speed than the Company's present cables, and is to be of special strength to resist the action of ships' anchors in fishing waters.

Magnetism and Contact Potential Difference.—In a Paper on the electric conveyance of heat, says the *Engineer*, M. L. Houllevigue mentions that the difference of potential between a conductor and iron is different accordingly as the iron is magnetised or not. One joint of a copper-iron couple was brought into a magnetic field, and the other left out. Since this arrangement could not give rise to a steady current without creating energy, an opposing E.M.F. was to be expected between the variously magnetised parts of the iron. Such a difference of potential was, in fact, found, the balance being in favour of the less magnetised portions.

Dynamos and their Prime Movers.—A feature of some interest regarding the relative sizes of dynamos and the engines which are used to drive them, says the *Electrical World* of New York, is shown quite nicely in some exhibits at Chicago. In all cases where there is direct driving, or where a single engine drives a single dynamo, it may be assumed that the dynamo and its prime mover are practically of the same horse-power; when the prime mover is a steam engine it will be noticed that the difference between the sizes, floor space, &c., of the dynamo and the engine is very greatly in favour of the former, the proportions being, perhaps roughly, about as one to three, or at least as one to two.

Plane of Polarisation of Hertzian Oscillations.—A recent number of *La Lumière Electrique* contains an article on this subject by M. Righi, in which he draws the following conclusions: his experiments with the metallic reflection of the oscillations tend to show that the plane of polarisation of electric oscillations is perpendicular to the direction of the magnetic forces, that is, parallel to that of the electric forces; but the experiments with reflection and refraction in dielectrics, on the contrary, tend to show that the plane of polarisation is perpendicular to the direction of the electric forces; the second being in accord with theoretical results, he thinks it is preferable to consider it as the true conclusion.

Huddersfield.—The electric lighting station was officially opened, and the supply of energy commenced last July. The number of consumers then connected was 33, or equivalent to 2,200 8-c.p. lamps. Since that time the number of consumers now connected has increased to 84, equivalent to 6,800 8-c.p. lamps, and many more premises are being fitted up, and will immediately require connecting with the supply mains. The total length of conduit laid for high-pressure mains is 12,000 yards, into which 5,420 yards of cable have been drawn. The total length of low-pressure mains laid is 5,305 yards. The number of junction boxes fixed is 127. The generating plant at the electric supply station is being increased by the addition of one engine and alternator, capable of supplying 6,600 8-c.p. lamps, which, with the existing machinery, will be ample to meet all demands during the coming winter.

West of Scotland Iron and Steel Institute.—The second ordinary meeting of the West of Scotland Iron and Steel Institute was held on Friday evening last, in the Technical College, Glasgow, Mr. James Riley presiding. Mr. E. J. Duff, manager, Blochairn Steelworks, read a Paper on "Electric Welding," in which he described various electrical processes in use for the welding of metals. He predicted a useful future for these processes, and said that they would admit of the accomplishment of many things that had in the past been impracticable. The processes were yet but little known in this country amongst engineers and ironworkers. He hoped that the information imparted by the lecture might in some degree be the means of calling attention to a subject well worthy of the consideration of all engineers and metallurgists.

Coupling Alternators in Parallel.—M. Staner, in some recent numbers of *L'Electricien*, gives a mathematical discussion of this subject, which is intended to determine the conditions which should be complied with in order that the coupling of the alternators may be as stable as possible; he treats the subject algebraically and graphically, and comes to the following conclusions:—That the external circuit should have as small a self-induction as possible, a condition which is at the same time a favourable one for the transmission of the energy; that the alternators should have as low an internal resistance as possible, which is also a condition favourable to efficiency; that the coefficient of self-induction of the alternators should have a certain value for which he gives the equation; where the self-induction of the external circuit is negligible, this equation reduces to $m\,l = \sqrt{r\,R'}$, in which m is equal to $2\,\pi$ divided by the time of the duration of one period, r the internal resistance of the alternator, and R' equal to the sum of the internal resistance and twice the external.

Inspection of Telegraph Messengers.—Nearly 900 telegraph messengers paraded at the Tower by 9 a.m. on Monday last for inspection by the Postmaster-General. The boys carried carbines, and presented a very workmanlike appearance, wearing gaiters and great coats with waist-belt and buckle outside. Every London district was represented by at least one company of 25 file. In addition to this the Central Telegraph Office sent two and the Indoor Boy Messengers one company. The parade was under the command of Lieut.-Col. J. P. MacGregor, and was mainly composed of those boys who have been selected as prize-winners for proficiency at drill and for general good conduct during the current year. After the customary salute with presented arms, the battalion marched past in column and quarter-column, music being provided by the massed bands of the Central Telegraph Office and the various districts. The Postmaster-General and Mr. Spencer Walpole (the new Secretary) were present; as were also several of the Metropolitan district postmasters.

A Gallant Savant's Definition of Electricity.—Prof. Galileo Ferraris was recently asked by a young lady what electricity was, but, unlike most others when asked that question, he ventured to answer it, and according to "Cosmos," wrote in French in her autograph book the following, of which we venture to give a translation, even though the English language hardly does justice to the original in French:—

"Maxwell has demonstrated that luminous vibrations can be nothing else than periodic variations of electromagnetic forces; Hertz, in proving by experiments that electromagnetic oscillations are propagated like light, has given an experimental basis to the theory of Maxwell. This gave birth to the idea that the luminiferous ether and the seat of electric and magnetic forces are one and the same thing. This being established, I can now, my dear young lady, reply to the question that you put to me: What is electricity? It is not only the formidable agent which now and then shatters and tears the atmosphere, terrifying you with the crash of its thunder, but it is also the life-giving agent which sends from heaven to earth, with the light and the heat, the magic of colours and the breath of life. It is that which makes your heart beat to the palpitations of the outside world, it is that which has the power to transmit to your soul the enchantment of a look and the grace of a smile."

The Yorkshire College Engineering Society.—The first ordinary meeting of this session, says the *Engineer*, was held on Monday, October 30th, when Prof. Hele-Shaw gave an address on "The Methods of Graphical Calculation." The lecturer showed that the chief uses of graphical workings were:—Firstly, the interpolation of unknown values from known values of a like kind; and secondly, the graphic representation of the rate of changes of two variable quantities. The elaboration of these two statements form the groundwork for the theory and application of all graphical methods. It was also pointed out that the limit of usefulness of graphical work was reached in dealing with two variable quantities of unlike kind, and that if it was required to depict graphically the rate of change between three variables of unlike kind it would be necessary to have not only area enclosed by the diagram, but volume. This was clearly shown by a plaster cast, which served to illustrate the uselessness of attempting to deal adequately with three variables of unlike kind by graphical methods upon plane surfaces.

Intensities of Lighthouse Lights.—Last Friday the second meeting of a Conference of the General Lighthouse Authorities of the United Kingdom and their engineers, together with representatives of the Admiralty and Board of Trade, was held at the Trinity House, at which it was decided to publish in the Official List of Lights, the candle-power of each light as determined by the engineers. By this means mariners will be informed of the relative illuminating powers of all the principal lights on the coast. The members of the Conference were Sir Sydney Webb, Deputy Master of the Trinity House, in the chair; Vice-Admiral Sir George Nares, of the Board of Trade; Captain Wharton, R.N., Hydrographer to the Admiralty; Sir Robert Ball, scientific adviser to the Irish Lighthouse Board; Captain Burne, Elder Brother, and Mr. Charles A. Kent, secretary of the Trinity House; Sheriffs D. B. Hope and R. N. Campbell, Northern Lighthouse Commissioners; Messrs. W. Watson and G. B. Thompson, Commissioners of Irish Lights; with Mr. T. Matthews, Mr. D. A. Stevenson, and Mr. W. Douglas, the engineers of the English, Scotch, and Irish Lighthouse Boards respectively. Mr. E. Price Edwards acted as secretary to the Conference.

Modification of the Violle Standard of Light.—The Reichsanstalt, at Berlin, has published a report on the use of fused platinum as a standard of light. It is well known that M. Violle has proposed to use a square centimetre of surface of glowing platinum at the point of solidification, for this purpose. The chief objections to this standard are that it is necessary to have the metal absolutely pure and, in order to have the surface absolutely smooth, that there should be a considerable quantity of metal in a molten state. An error of 10 per cent. is very frequently present. The Reichsanstalt has, says the *Revue Scientifique*, ventured to standardise the temperature of the platinum quite independently of its melting point. It has been proved that at a certain fixed temperature the proportion of the total radiation which is transmitted through a layer of pure water of a definite thickness is always equal to 2 per cent., whatever the thickness of the platinum. This might have been expected. In order to measure the amount of luminous radiation, a very sensitive volometer has been constructed, the parts being composed of strips of platinum of one millimetre width and of extremely small thickness, said to be one-thousanth of a millimetre.

Electricity in Sugar Refining.—An account has been given by Von Lippmann of his observations when inspecting a certain sugar factory. The purification of beetroot juice was done, says the *Engineer*, by means of electricity. The warm diffusion juice is subjected to a current of 30 to 40 amperes at a pressure of 4 to 5 volts from a Siemens dynamo machine between electrodes of sheet zinc. A thick, muddy precipitate, which gradually sinks to the bottom of the vessel, separates at the anode. The electric current effects the coagulation of the albumen, which carries down many other substances; the zinc oxide which is formed combines also with numerous organic substances; and, as a matter of fact, the mud which separates at the electrode contains zinc oxide to the extent of one-third of its weight, but the juice is quite free from zinc. As, however, the diffusion juice does not contain much albumen, and the zinc plates are said to last for eight days and longer, it is impossible that the chemical effect can be great. It is, therefore, difficult to say, in the absence of analytical data, whether the excellence in purity of the sugar turned out at the factory in question is due to the application of electricity, or whether a judicious coagulation of albumen before purification would not lead to equally good results.

A Seismic Photochronograph.—In *L'Elettricista* for November, Dr. A. Cancani describes an instrument for recording photographically the precise time at which an earthquake shock is felt at the observing station. This is done by obtaining a photograph of the face of a chronometer at the instant of the shock. In the apparatus in question the chronometer is illuminated for an instant by an incandescent lamp thrown into circuit by any one of the seismic instruments in the observatory. The mechanism, which is rather complicated, consists essentially of a horizontal lever carrying a pan with nine potassium bichromate pots on one arm, while the other is provided with weights, and is kept in position by the raised armature of an electromagnet. When the circuit of the latter is completed by one of the seismoscopes, the armature is attracted, the bichromate pots are raised, and the zinc-carbon couples fixed above them are immersed in the liquid, thus supplying the current for the lamp. After about a quarter of a second the lamp circuit is broken by one of the weights sliding off the lever, and the whole apparatus is automatically readjusted for the next shock. It has been in use at the Rocca di Papa Observatory, and has worked well.

The Junior Engineering Society.—Last Friday evening, at the Westminster Palace Hotel, the inaugural meeting of the thirteenth session of this Society took place, and was largely attended. The retiring President (Dr. John Hopkinson, F.R.S.) took the chair at the commencement of the proceedings, and, after some formal business had been disposed of, presented the Society's premium to Mr. R. W. Newman for his Paper on "The Sanitary Engineering of Dwellings." A vote of thanks having been cordially passed to Dr. Hopkinson for his services as President, the new President (Mr. J. Wolfe Barry, Vice-President Inst. C.E.) was then introduced, and proceeded to deliver his Presidential Address, an abstract of which will be found in another column. The hearty thanks of the Society having been expressed to the President for his address, the meeting terminated with the announcement of the ensuing meeting, when a Paper will be read by Mr. S. Cutler, jun., on "Coal Gas Manufacture and Recent Improvements in the Plant Employed therein." Other Papers on the session's programme are "Boiler Incrustations and Deposits," by Prof. V. B. Lewes; "The Construction and Working of Electromotors," by Mr. A. H. Dykes; "The Design and Construction of Boilers for Locomotive Engines," by Mr. G. F. Burtt; "Lubricants: their Use, Testing, and Analysis," by Mr. W. F. E. Seymour; "The Industries of Devon and Cornwall," by Mr. F. R. Taylor; "Marine Engineering Repairs," by Mr. T. P. Hosegood. Visits to works take place between the meetings, the Papers and reports of visits being printed in the Society's record of transactions. We may add, for the information of any of our readers desiring particulars of membership, that the address of the Secretary is 47, Fentiman-road, S.W.

Toronto.—The electric companies of Toronto, says the *Canadian Electrical News*, are brought face to face with a difficulty which threatens to make serious inroads upon their profits, if indeed it does not in some instances wipe them out altogether. We refer to the action of the city assessment department in placing an assessment for the first time this year on the plant of these companies. In the case of the Toronto Electric Light Company, this assessment amounts to about $300,000, and calls for the payment of $7,000 yearly in taxes, or about one-fifth of the Company's total income. It is not difficuit to realise what a tremendous burden this would be on almost any class of business, and on none perhaps would it fall more heavily than on electric lighting companies, as it is a well-known fact to all who are familiar with the conditions, that excessive competition has reduced the profits of the business to a minimum. Electric lighting companies are under contract with the municipalities to furnish light at a certain fixed price for a definite number of years, and therefore it will be impossible for them to make good their loss by increasing prices, at least so far as street lighting is concerned. Even were this not the case they are obliged in many instances to maintain a price which will compete with gas. A most serious injustice with which the electric companies have to contend in competition with gas companies is, that under the assessment law the underground mains of the gas companies are exempt from taxation. Thus even in cases where, as in that of the Incandescent Light Company, of Toronto, the distribution of current is done by means of underground conduits, the electric light company's mains will be taxed while those of the gas company's will escape assessment. In a variety of ways, therefore, the electric companies are placed at a serious disadvantage, and unless in some way they can be relieved of this latest burden their already slender profits will as already stated in many instances be wiped out altogether. Another hardship is that there is but one appeal from the decision of the Court of Revision, viz., to the county judge, whose decision is final. Should the efforts which will be made by the electric companies in Toronto to be relieved of this method of assessment prove unavailing, then a united effort on the part of all the electrical companies of the province should be made at the next session of the Ontario Legislature to have the matter remedied.

The Niagara Electric Plant.—After protracted and exhaustive examination of many plans submitted by various electrical companies in America and Europe, the Niagara Falls Power Company announces, says the *Electrical World* of New York, that it has awarded to the Westinghouse Company, of Pittsburgh, Pa., a contract covering the construction and erection of three alternating current dynamos of 5,000 H.P. each, after designs originating with the engineers of the Cataract Construction Company, and especially adapted to the particular requirements of the hydraulic works of the Niagara Falls Power Company. The system adopted involves the use of two-phase current, with a frequency of 25 periods per second, generated at a voltage of 2,000 and the use of transformers for long distance transmission at higher pressure. The officers of the Cataract Construction Company include the following well known business men: Edward D. Adams, who is president; Francis L. Stetson, Edward A. Wickes, William L. Rankin, and Dr. Coleman Sellers as engineer, with Prof. George Forbes, of London, as consulting engineer. The Cataract Construction Company has been conducting negotiations with the principal electric manufacturing companies, including the Westinghouse Electric and Manufacturing Company, the Siemens and Halske Company and the General Electric Company. Early in the spring of the present year bids were received based upon specifications advocated by the individual companies, in which the different companies were at liberty to advocate the different systems and class of machines which they preferred. The system finally adopted was the two-phase alternating current, Tesla system. After a careful study of the conditions under which the apparatus had to operate, the engineers of the Cataract Construction Company prepared a complete set of specifications calling for the employment of the two-phase system, new proposals were submitted, and the contract was awarded to the Westinghouse Electric and Manufacturing Company, as above stated. The machines will be built in units of 5,000 H.P. The revolving field of the generator will be constructed with inwardly projecting poles, and will revolve in a horizontal plane, being mounted upon the vertical shaft of the turbine. The weight of the shaft, turbines, and armature is to be carried by the upward pressure of the water columns producing the heads for the turbines. The electromotive force generated will be 2,000 to 2,400 volts, and will be increased by step-up transformers for long-distance transmission, and lowered by reducing transformers for distribution. The motors will be the two-phase Tesla motors, which have been found to be well adapted for power purposes although this question is not definitely settled. The system adapts itself readily to the use of motor generators or rotary transformers, so that it is possible to develope either single-phase alternating currents or continuous currents of any desired electromotive force, as may be required for the use of individual customers. It is expected that a large amount of power will be employed for manufacturing purposes, arc and incandescent lighting, electrolytic work and power purposes generally. It is also understood that the Company contemplates sending currents at high pressure to Buffalo and greater distances, to be used for lighting and power purposes. The work upon the apparatus has already been begun, and it will be erected at the earliest possible date.

ELECTROMAGNETIC THEORY.—LIX.

BY OLIVER HEAVISIDE.

(*Continued from page 7.*)

§ 219. In any electromagnetic combination the effects of electric and magnetic energy are antagonistic in some respects. Or we may say that magnetic inductances tend to neutralise electric permittances. Or, more generally, that the effects of elastic compliance and of inertia tend to neutralise one another. Thus, when a coil is under the action of a simply periodic voltage, the current lags, owing to the self-induction. But if a condenser be introduced in sequence with the coil, the lag is diminished, and may be reversed or converted into a lead. The result on the current is the same as if we substituted for the coil another of the same resistance and of reduced inductance, or even of negative inductance. Thus, the resistance operator of the coil being $R+Lp$, where R and L are its resistance and inductance, and p is the differentiator d/dt; and that of the condenser being $(Sp)^{-1}$, where S is its permittance, when the two are in sequence the resistance operator of the combination is

$$Z = R + Lp + (Sp)^{-1}, \quad . \quad . \quad . \quad . \quad . \quad (1)$$

which, in a simply periodic state of frequency $n/2\pi$, making $p^2=-n^2$, or $p=ni$, becomes

$$Z = R + Lp - \frac{p}{Sn^2}$$

$$= R + \left(L - \frac{1}{Sn^2}\right)p. \quad . \quad . \quad . \quad (2)$$

This shows that the effective inductance of the condenser, which is $-(Sn^2)^{-1}$, is additive with real inductance when in sequence therewith, and being negative, reduces the effective inductance of the combination from L to $L-(Sn^2)^{-1}$.

But when the condenser and coil are in parallel, it is more convenient to use the conductance operators. Thus

$$Y = (R+Lp)^{-1} + Sp \quad . \quad . \quad . \quad . \quad . \quad (3)$$

is the conductance operator of the coil and condenser in parallel, being the sum of the conductance operators of the coil and condenser taken separately. And when $p=ni$, we convert Y to

$$Y = \frac{R-Lp}{R^2+L^2n^2} + Sp$$

$$= \frac{R}{R^2+L^2n^2} + \left(S - \frac{L}{R^2+L^2n^2}\right)p, \quad . \quad . \quad (4)$$

from which we see that the combination is equivalent to a condenser of conductance $R(R^2+L^2n^2)^{-1}$ and of permittance $S-L(R^2+L^2n^2)^{-1}$. The steady conductance being R^{-1}, we see that the effective conductance is reduced by the self-induction. At the same time the effective permittance is reduced, and may become negative. Remember that in (3) and (4) the standard of comparison is a condenser, not a coil; whereas in the former case (1), (2) the standard of comparison is a coil, not a condenser. For further information regarding resistance and conductance operators *see* "Electrical Papers," Vol. II., p. 355, and elsewhere. The present remarks are merely definitive and introductory to the theory of waves sent along a circuit, either naturally, or partly controlled by subsidiary arrangements. The comparison with a coil is, I believe, more generally useful. Then we imagine any combination to be replaced by a simple coil whose resistance and inductance are those (effectively) of the combination. But there are cases when the other way is preferable. Then we imagine the combination replaced by a condenser whose conductance and permittance are those (effectively) of the combination. And in the following it will be convenient to use both ways in the same investigation.

§ 220. Now imagine the permittance of a submarine cable to be concentrated in lumps at a number of points. Let S be the permittance of one of the equivalent condensers. If it be shunted by a coil of such R and L that $S=L(R^2+L^2n^2)^{-1}$, we know by the above that the state of the cable, when simply periodic, will be the same as if the condenser and coil were removed and replaced by a simple leak of conductance $R(R^2+L^2n^2)^{-1}$. This reasoning applies to every condenser, if it have its appropriate coil, or to any selected group we please. But if the frequency be changed the permittance will come into sight again, of the real or positive kind, or of the fictitious negative kind, as the case may be. We have, therefore, the power of reducing the effective permittance of a cable under simply periodic forces, by means of numerous auxiliary inductive shunts or leaks, and of practically cancelling it at a particular frequency. How will this work out in the transmission of telephonic currents through the cable?

From the purely theoretical point of view one may be somewhat prejudiced against the system at first. For, obviously, it is not a distortionless arrangement. That is got by balancing the self-induction of the main circuit against the lateral permittance, which can, subject to practical limitations, be done perfectly. That is, there is a balance at any frequency, or the idea of periodic frequency does not enter at all. I doubt whether there can be any other distortionless circuit than that which (in the absence of another) I always refer to as *the* distortionless circuit. With inductive shunts we produce a partial neutralisation of the permittance, the amount of which may vary very widely during the transmission of telephonic currents. Remember, too, that during the change from one frequency to another there are other phenomena than those concerned during the maintenance of a simply periodic state of variation.

Nevertheless, we should be careful not to be prejudiced against an imperfect plan merely because it is so manifestly imperfect. It may perhaps be more easily applied than a theoretically perfect system, and may possess practical advantages of importance. Now this is a matter for practical experiment and experience. But it is just here that there is an almost complete dearth of information. For although Prof. Silvanus Thompson has mentioned that he has made many experiments, yet he has only described one case in which an inductive shunt was found good. It was an artificial cable of 7,000 ohms and 10 microfarads. Presuming that there was a fairly good spreading of the permittance, we see that the permittance is that of about 40 kilometres of a submarine cable, whilst the resistance is more like that of 1,000 or 2,000 kilometres. The inductance would probably be very small. We see that the example does not well represent a submarine cable. We should rather compare it with a very long overland circuit of very much smaller permittance per kilometre than the cable. Only, such a circuit, if properly put up, would have a large inductance, so that there is a failure here. However, it is mentioned that one shunt of 312 ohms and a time-constant of 0·005 sec. rendered telephonic transmission possible except for shrill sounds. I cannot help thinking that Prof. Thompson has been much too reticent on the experimental side. He will perhaps furnish us with fuller information later on. At present there is little to judge by.

§ 221. In the meantime the following theory and formulæ may perhaps be useful to those who may desire to go into the matter. I put the theory into such a form that it may be applied to various other cases of auxiliary arrangements. Let V and C be the transverse voltage and the current, at distance x, at time t. Let their connections be

$$-\frac{dV}{dx} = ZC, \qquad -\frac{dC}{dx} = YV, \quad . \quad . \quad . \quad (5)$$

where Z is a resistance operator, and Y a conductance operator, as described in § 219, only now belonging to unit length of circuit. In the simplest case Z reduces to a resistance, and Y to a conductance, per unit length. But in general Z and Y may have various forms, in unlimited number, being then functions of electrical constants and of the time differentiator p. When there are no auxiliary devices, and the natural resistance R, inductance L, leakance K, and permittance S (all per unit length) are constants, then we have

$$Z = R + Lp, \qquad Y = K + Sp, \quad . \quad . \quad . \quad (6)$$

as before, § 201—4. But whatever the forms of Y and Z may be, in finite terms or transcendental, we may reduce them to the simple standard forms (6) when the simply periodic state of vibration is maintained, by employing the transformation $p=ni$, or $p^2=-n^2$. We see from this that we can practically examine cases of simple periodicity which might at first seem

Digitized by Google

beyond all bounds of practicability. Note, however, that "forces" and "fluxes" should be in constant ratios, so that such phenomena as hysteresis, magnetic or electric, are excluded.

From equations (5) we see that the characteristic equation of V is
$$\frac{d^2V}{dx^2} = YZV = q^2V, \text{ say}, \quad . \quad . \quad . \quad . \quad (7)$$
provided Y and Z are independent of x. This restriction is not a necessary one, but, of course, it makes an important practical simplification to have uniformity along the circuit. In (7) q^2 represents the operator YZ, and in passing we may notice an interesting matter connected with partial differential equations of the type (7), or of the more general type
$$\nabla^2V = q^2V, \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$
appropriate to three dimensions in space. This type of equation occurs in all sorts of physical problems, V being some variable which is propagated through a medium in a manner depending upon the nature of the operator q^2, which involves the time-differentiator. It is usually a very simple rational function of p, such, for example, as to bring in only the first and second derivatives of V with respect to the time, and, so far as I know, no physical problems have presented themselves which involve an irrational partial differential equation for characteristic, as, for example,
$$\nabla^2V = (a + bp + cp^2)^{\frac{1}{2}}V. \quad . \quad . \quad . \quad . \quad (9)$$

It might, indeed, seem at first sight that a characteristic of this form was physically impossible, being meaningless. Nevertheless, it is quite easy to see by the way equation (7) was constructed out of the components (5), that real physical problems may involve irrational characteristic equations, such as are exemplified by (9). For if either Y or Z be irrational, so is YZ. And we can easily (in imagination, not so easily in execution) choose auxiliary devices making Y or Z irrational. Similar remarks apply to (8). It results from the union of two distinct equations involving two variables, one of which is then eliminated to make the characteristic. If either of the component equations involves an irrational operator, the characteristic resultant will be irrational. It must not be imagined that the solutions of such equations obtained by physical reasoning are impossible or beyond the range of mathematics, or that the results are physically meaningless. Some partial characteristics of the form (8), with irrational right members, I have examined and solved. I should imagine that there will probably be a field for equations of the kind in the future study of the complicated influence of matter upon phenomena which occur in their simplest manner in the ether away from matter, as in the theory of dispersion of light, for example, of electric absorption, and in similar subjects.

Returning to equation (7), the general solution involves two arbitrary functions of the time, as in the form
$$V = \cosh qx.V_0 + \frac{\text{shin}\, qx}{q} ZC_0. \quad . \quad . \quad . \quad . \quad (10)$$
But it is preferable to take the case of disturbances propagated from a source into an infinitely long cable, in order to eliminate complications due to reflections and terminal apparatus. Then
$$V = \epsilon^{-qx}V_0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$
is the solution representing V at x, t due to V_0 given as a function of the time at $x = 0$, the origin. And the current is given by
$$C = \frac{q}{Z}V = \left(\frac{Y}{Z}\right)^{\frac{1}{2}}\epsilon^{-qx}V_0, \quad . \quad . \quad . \quad . \quad (12)$$
by using the first of (5).

To see the final state due to the continued action of constant V_0, give q, Y, and Z in (11), (12), the values they assume when p is put $= 0$ in their general expressions, viz., for Y the steady leakance and for Z the steady resistance per unit length, and for q their geometric mean. To find how this state is arrived at, and, more generally, to interpret (11), (12) where V_0 is any given function of the time, demands the conversion of these equations to proper algebraical form by execution of the analytical operations implied in q, Y, and Z. This we are not concerned with here, except as regards the case arising when V_0 is a simply periodic function. Then put $p = ni$, and reduce Z to R + Lp, and Y to K + Sp, as before stated, equations (6), making (11), (12) become
$$V = \epsilon^{-qx}V_0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$
$$C = \left(\frac{K + Sp}{R + Lp}\right)^{\frac{1}{2}}\epsilon^{-qx}V_0, \quad . \quad . \quad . \quad . \quad (14)$$
where
$$q = (R + Lp)^{\frac{1}{2}}(K + Sp)^{\frac{1}{2}}. \quad . \quad . \quad . \quad . \quad (15)$$

These expressions have next to be reduced to the form $(A + Bp)V_0$, which is a matter of common algebra. When done we shall find that if
$$P \text{ or } Q = (\tfrac{1}{2})^{\frac{1}{2}}\left[(R^2 + L^2n^2)^{\frac{1}{2}}(K^2 + S^2n^2)^{\frac{1}{2}} \pm (RK - LSn^2)\right]^{\frac{1}{2}}, \quad . \quad (16)$$
then the V solution is
$$V = e\,\epsilon^{-Px}\sin(nt - Qx), \quad . \quad . \quad . \quad . \quad . \quad (17)$$
due to $V_0 = e \sin nt$ at the origin. From this, by the use of the first of (5), giving
$$C = \frac{-\dfrac{dV}{dx}}{R + Lp} = -\frac{R - Lp}{R^2 + L^2n^2}\frac{dV}{dx}, \quad . \quad . \quad . \quad . \quad (18)$$
we may derive the C solution. Or we may derive it by developing (14). The result is
$$C = \frac{e\,\epsilon^{-Px}}{P^2 + Q^2}\left[(KP + SnQ)\sin + (SnP - KQ)\cos\right](nt - Qx), \quad (19)$$
where the value of $P^2 + Q^2$ is given by
$$P^2 + Q^2 = (R^2 + L^2n^2)^{\frac{1}{2}}(K^2 + S^2n^2)^{\frac{1}{2}}. \quad . \quad . \quad (20)$$

It may be only necessary to consider the amplitudes of V and C, and, of course, C is most important. That of V is obviously $e\,\epsilon^{-Px}$, by (17). That of C may be got from (19), and is expressed by
$$(C) = e\left(\frac{K^2 + S^2n^2}{R^2 + L^2n^2}\right)^{\frac{1}{2}}\epsilon^{-Px}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (21)$$

The wave speed is n/Q, the wave length $2\pi/Q$, and the periodicity $n/2\pi$. Another convenient form of (21) is
$$(C) = \frac{e}{Lv}\epsilon^{-Px}\left(\frac{1 + K^2/S^2n^2}{1 + R^2/L^2n^2}\right)^{\frac{1}{2}}, \quad . \quad . \quad . \quad . \quad . \quad (22)$$
where $v = (LS)^{-\frac{1}{2}}$.

§ 222. The above simply periodic solution is discussed in my "Electrical Papers," Vol. II. (especially p. 396 and p. 339) where R, L are the natural effective resistance and inductance and K, S the leakance and permittance per unit length, the latter pair being supposed to be the same at all frequencies (A Paper by Prof. Perry, *Phil. Mag.*, August, 1893, may als be consulted, but I do not think he is right in some of hi conclusions.) But the same formulæ are applicable whei auxiliary devices are employed, if they are numerous enough by a process analogous to the obvious one of representing large numbers of separate leaks by uniform leakance.

Thus, in the case of inductive shunts, if we treat them as a set of separately located shunts, the full theory is very complicated, because it requires a separate formula for every section of the line. The best course to take is to distribute the inductive leakance uniformly, in imagination, of course. The result will represent the fullest possible carrying out of the principle concerned, and more. Thus, let ρ be the resistance and λ the inductance of the leak belonging to the unit length of cable. The reciprocal of ρ is of course the steady leakance per unit length. But it does not operate fully when the stat is changing, owing to λ. We shall now have
$$Y = \frac{1}{\rho + \lambda p} + \sigma p, \quad . \quad . \quad . \quad . \quad . \quad (23)$$
where $(\rho + \lambda p)^{-1}$ is the leakance operator, taking the place c ρ^{-1}, whilst σ is the steady permittance per unit length. W have to use this special Y in the above formulæ to represen the effect of inductive leakage. In the simply periodic cas Y develops to
$$Y = \frac{\rho}{\rho^2 + \lambda^2n^2} + \left(\sigma - \frac{\lambda}{\rho^2 + \lambda^2n^2}\right)p. \quad . \quad . \quad (24)$$
The first term is the effective leakance, and the coefficient of p the effective permittance per unit length.

In the developed formulæ (16), (17), (19) to (22), therefor we must give K and S the values
$$K = \frac{\rho}{\rho^2 + \lambda^2n^2}, \qquad S = \sigma - \frac{\lambda}{\rho^2 + \lambda^2n^2}, \quad . \quad (25)$$

Digitized by Google

to suit the case of inductive leakage, whilst R and L remain as before, the effective resistance and inductance per unit length of line. The solutions should be examined through a wide range of frequency in order to arrive at a good knowledge of how the circuit would behave to telephonic currents, with different values of λ and ρ. It is, of course, necessary that ρ should not be so small as to produce too great a loss in transit.

Notice that λ and ρ are immensely big when the unit length is a centimetre. Remember that m equal coils in parallel behave like one coil of one m^{th} the resistance and inductance of the individual coils. Thus, when ten shunts at the rate of one per kilometre take the place of one shunt per ten kilometres, each of the ten should have ten times the resistance and inductance of the one. This leads to physically monstrous results when we do as was done above, and make the action uniform, as it implies infinitely large inductance of an infinitely small section of the leakance. But that need not cause any alarm when we are employing the ideal case for calculating purposes. What is more important is that a stop would soon be set to the multiplication of the shunts.

At the particular frequency making the effective permittance vanish, the solution may be obtained simply from the fundamental formulæ, since Y reduces to a constant, viz., the value of K in (25), S being zero; and only the rationalisation of Z has to be attended to. If, further, we assume that L = 0, then Z is also constant, viz., R, and the solutions are simply

$$V = \epsilon^{-x(RK)^{\frac{1}{2}}} V_0, \quad . \quad . \quad . \quad . \quad . \quad (26)$$

$$C = \left(\frac{K}{R}\right) V. \quad . \quad . \quad . \quad . \quad . \quad (27)$$

These represent a very remarkable state of affairs throughout the cable. But it is thoroughly deceptive, because even if the inductance of the line were quite unimportant under normal conditions, the effective cancellation of the permittance would make it important under the present circumstances; that is, L cannot be neglected. Including it, when S = 0, the value of P reduces to

$$P = (\tfrac{1}{2})^{\frac{1}{2}} \left(\frac{\rho}{\rho^2 + \lambda^2 n^2}\right)^{\frac{1}{2}} \{R + (R^2 + L^2 n^2)^{\frac{1}{2}}\}^{\frac{1}{2}}, \quad . \quad (28)$$

and the current amplitude, according to (21), becomes

$$(C) = \frac{\rho^{\frac{1}{2}} \epsilon^{-Px} e}{(\rho^2 + \lambda^2 n^2)^{\frac{1}{2}} (R^2 + L^2 n^2)^{\frac{1}{4}}}, \quad . \quad . \quad . \quad (29)$$

in which, of course, ρ and λn are not independent, having a relation fixed between them by the vanishing of S in (25). By giving a suitable value to σ, for instance, $\frac{1}{4}$ microfarad per kilometre (which is a suitable unit of length to employ), and also fixing the frequency, we may readily apply the formulæ to estimate the attenuation with different values of the insulation resistance or its equivalent.

(To be continued.)

PHOTOMETRIC FANTASIES.

Under this title M. Hospitalier comments in *L'Industrie Electrique* on the discussion which has recently appeared in our columns on power of search lights, or intensity, as Mr. Steinmetz calls it. The discussion arose out of a remark made in Prof. S. P. Thompson's article on the Chicago Congress (*The Electrician*, September 20, 1893). M. Hospitalier quotes the remark, together with Mr. Steinmetz's letter and our Notes on the subject, in full, and continues :—

"The discussion which we now resume proves as far as the evidence goes, that the photometry is on a fundamentally wrong basis, and that it is absolutely impossible to compare and to express as the function of one and the same unit, the luminous intensity of a *source* of light reduced theoretically to a mathematical point, and that of a luminous beam of which the rays are parallel or sensibly so. Indeed, in the first case, the illumination diminishes directly as the square of the distance; in the case of parallel rays, the illumination remains constant, neglecting the absorption of the atmosphere. The more the source of light is withdrawn, of which the rays have been made parallel, the greater the luminous intensity, calculated in the ordinary way, increases; it increases, too, beyond all limit, which is physically impossible.

"To take analogy from phenomena familiar to electricians, a luminous *source* is comparable to *magnetic pole*; the field which it produces varies inversely as the square of the distance: a parallel luminous beam is comparable to a uniform magnetic field. But the intensity of a magnetic pole is equivalent to the flux of magnetic force, while the intensity of the field is the quotient of a flux of force by a surface. These two physical quantities of different nature are incommensurable.

"The expression of the intensity of a magnetic pole capable of producing a magnetic field of a given intensity has not any physical meaning, and this is the corresponding photometric expression which is used by the inventors and constructors when they speak of a lighthouse or of a projector producing so many millions of candle-power. Even taking into account the divergence of the rays, and of the imperfection of the projector, the photometric measurement loses all meaning, because of the want of physical identity between the magnitudes purported to be measured in the two cases.

"We conclude, then, against Mr. Steinmetz, and with our contemporary *The Electrician*, that the values of the luminous intensities attributed to lighthouses and to projectors have not any physical meaning.

"On this point, as well as on many others, photometry must be entirely revised. This conclusion allows us to dispense with the objection of Prof. Silvanus Thompson about the surface of the crater, which should give an arc of 180,000,000 candle-power, an objection which we have not reproduced because it only begs the question."

After so lucid an explanation such as M. Hospitalier is wont to give, especially upon subjects on which others are be-fogged, it is hardly necessary to add another word. The analogies which he draws between candle-power and the strength of a magnetic pole, and between illumination and the intensity of a magnetic field, are very apt. The importance of magnetic poles is merely due to the fact that they are associated with lines of force, the number of lines being proportional to the strength of the pole. An ordinary source of light diverges its rays uniformly in all directions, just as a magnetic pole emits lines of force. When these lines or rays cease to diverge and become parallel, it is useless to speak any longer of the former being due to a magnetic pole, or the latter to a light source fixed at a finite distance. It is far better to consider the density of these lines or rays, *i.e.*, the induction density of the magnetic field, in the one case, and the density of the rays of light, or the illumination of the optical field in the other. Rays of light can in fact be treated in exactly the same way as lines of force. A ray of light can always be supposed to represent a definite quantity of light just as a line of force always denotes a fixed quantity of magnetic induction.

We may mention, however, that another discussion has been going on in the *Electrical World* of New York. Prof. S. P. Thompson's remark found its way into the "Digest" of the *Electrical World* of New York, and was accompanied by a comment by Mr. Carl Hering. To this Mr. Steinmetz replied in much the same terms as his letter which appeared in our columns, and to this Mr. Carl Hering makes a rejoinder, demolishing the fallacy. "If Mr. Steinmetz," he concludes, "can describe how calculations of the candle-power of search lights from photometric measurements are made in practice by those well up in the subject, the matter would, doubtless, be of great interest to many; I have inquired of the United States Naval Department, as also have several of the most prominent makers of search lights in Europe, but without obtaining any satisfactory replies."

We should not have called attention again to the subject but for an official announcement which has been made regarding the photometry, or at all events the designation, of the power of British lighthouses. In this announcement, which will be found in our Notes, it is promised that "the candle-power of each light, as determined by the engineers," will be published in the Official List of Lights. "By this means mariners will be informed of the relative illuminating powers of all the

Digitized by Google

principal lights on the coast." If the "relative" illuminating powers be adhered to there need be no confusion. The sizes of lighthouse lanterns have long been designated as "first order," "second order," &c., a classification as unfortunate as that of levers in text-books on mechanics. The sizes would be much better expressed simply by the diameters. For the illuminating power, some such arbitrary system would probably be the best. The sailor would, probably, prefer to call a light "a No. 3," than a "14,000 candle-power," especially as it is clear that the 14,000 candle-power is quite fallacious. The most powerful light might be called No. 1, and the lesser ones 2, 3, &c., as the magnitudes of stars are described. When the time comes for bigger lights they can be called No. 0, No. 00, &c., as in the wire gauge. The effect of atmospheric absorption, however, will seriously interfere with the apparent brilliance of the lights, and if, as there is every reason to suppose, electric lights suffer more than oil lights in thick weather, the advantage of designating the power of lighthouses is considerably reduced.

NODAL SYSTEMS OF ELECTRIC WAVES OBTAINED BY LECHER'S METHOD.*

BY DOMENICO MAZZOTTO.

This Paper gives the results obtained in an investigation of the various wave systems produced in a Lecher wire system† on varying the lengths of the primary and secondary wires, and the round india-rubber tubes sliding on the secondary wires, and approaching each other to within a distance of 2cm. When the apparatus was worked in the dark, and the fingers were brought near the platinum tips of the wires, two small luminous stars appeared at these tips when the bridge was in the vicinity of a node, and on further approaching the node these stars became very bright and conspicuous sparks, even without the presence of the fingers. This "explorer" has the advantage over Lecher's tube of showing more decided maxima and minima, being less fatiguing to the eyes, and less capricious in its action.

The condenser plates used by Signor Mazzotto were of zinc, 40cm. square, and 0·25cm. thick. The primary and secondary wires were soldered to the upper extremities of their near edges, 12cm. apart, and consisted of copper wire, 1mm. thick. The distance between the condenser plates could be easily varied between 1cm. and 15cm. The maximum length of the primary wires was 2·42m., and that of the secondary wires 25m.

The main object of the investigation was to find a ready way of unravelling the multitudinous nodal systems formed when the induction system—*i.e.*, the primary wires and the condenser—was kept constant, and the secondary wires bridged in different places. The multiplicity of these nodal systems was found to be greater than what would appear from Lecher's work. The "harmonics" of the fundamental system were not the only higher systems that were produced; but it was possible, by altering the disposition of the bridges, to produce any system intermediate between two harmonics. It was also found, however, that when the second bridge was placed in a certain position, the nodal systems obtained by shifting the first bridge were independent in position and intensity of the state of the system beyond the second bridge and behaved just as if the wires were cut off and joined by the second bridge. In order, therefore, to find all the possible nodal

Fig. 1.

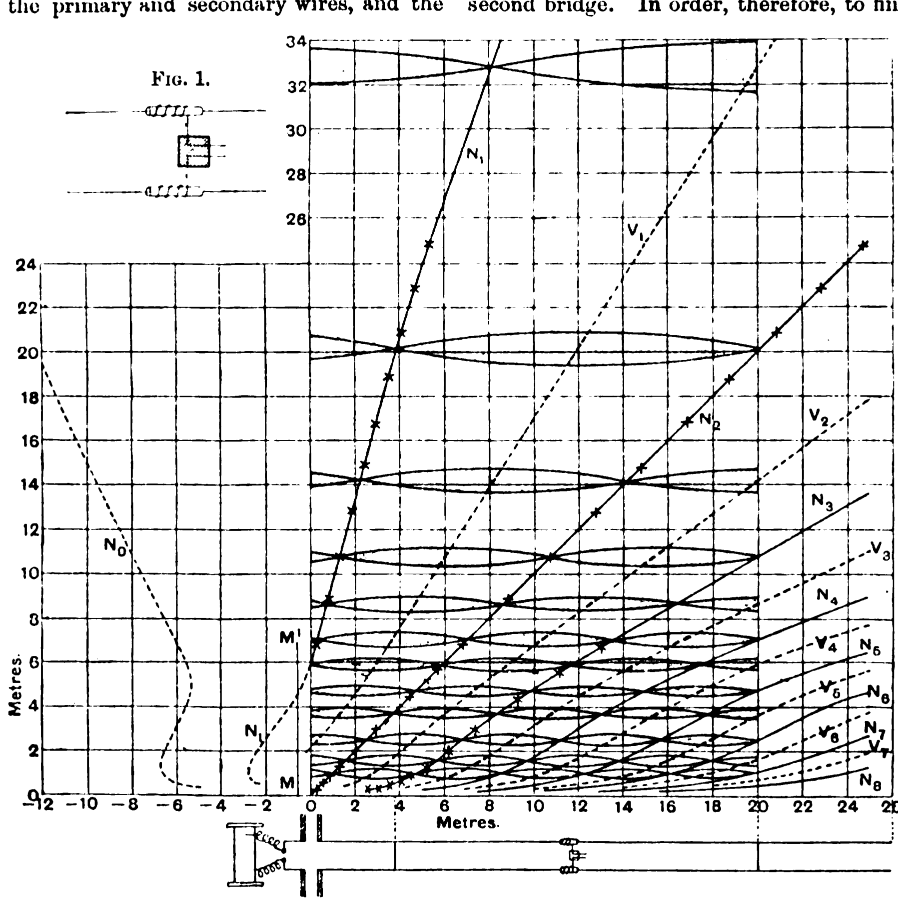

Fig. 2.—Distance between Plates, 5cm. Length of Primary Wires, 62cm.

distance apart of the plates of the condenser. The wire system in question is sketched at the bottom of Fig. 2. It consists of two metallic plates, joined by means of metallic wires (primary or adductor wires) to the knobs of a spark-gap, which are further connected with the terminals of an induction coil. In front of the primary plates are two equal and parallel plates connected with secondary wires. Two opposite points in the latter can be connected by a "bridge" capable of being shifted along the wires.

The points of maximum difference of potential along the wires were indicated, not by a Geissler tube, as in Lecher's experiments, but by an "explorer," consisting of two wires (Fig. 1) passing systems, it sufficed to find them for all possible positions of the second bridge. Each system is sufficiently defined if two of its nodes are known, since all the nodes are equidistant. Taking then, any one system, and noting its development as the second bridge is moved away from the zinc plates along the wires, and plotting the "nodal lines," we obtain Fig. 2, where the distances from the plates are taken as abscissæ, and the distances of the second node (N_2) of each system as ordinates.

In practice, points along the nodal lines are determined as follows: The second bridge is placed at the end of the secondary wires, and the first bridge is shifted from the vicinity of the plates towards the second, keeping the "explorer" always half way between the bridges. They are shifted until the maximum effect is obtained at the explorer, showing that the system of waves producing it h

† *Wiedemann's Annalen*, Vol. XLI., p. 850, 1890.

Digitized by Google

the greatest possible wave-length. This is usually accomplished at the first trial, and tested by the gradual extinction of the glow on approaching the explorer to either of the bridges. The position of the first bridge is noted, and the second is shifted by a convenient amount in the direction of the plates. The corresponding position of the first bridge is determined as before, and the process continued until the bridges are inconveniently close to the plates. When that happens they are shifted by one wave-length, and then the second bridge will indicate the position of the third node (N_3), and its successive positions will trace a third "nodal line."

Other nodal lines (N_4, N_5, &c.) are easily obtained by cutting off equal segments along the abscissæ, and joining the points of section, and lines denoting the centres of ventral segments (V_1, V_2, &c.) are obtained by joining points midway between the nodes.

To determine all the possible systems for any given position of the second bridge, cut off its distance along the axis of abscissæ, and draw an ordinate, cutting the various nodal lines. From the points of intersection draw horizontal lines towards the left. These will represent the various systems, and twice the distance between two successive nodes will be the corresponding wave-lengths.

The dotted lines (N_0 and a portion of N_1) are obtained by cutting off corresponding segments beyond the first bridge towards the inductor. The lengths of abscissæ cut off by these lines may be taken as the equivalent lengths of the inductor system.

Besides this system of nodal lines others were determined with the plates at distances apart of 1, 2, 5, and 15cm., and

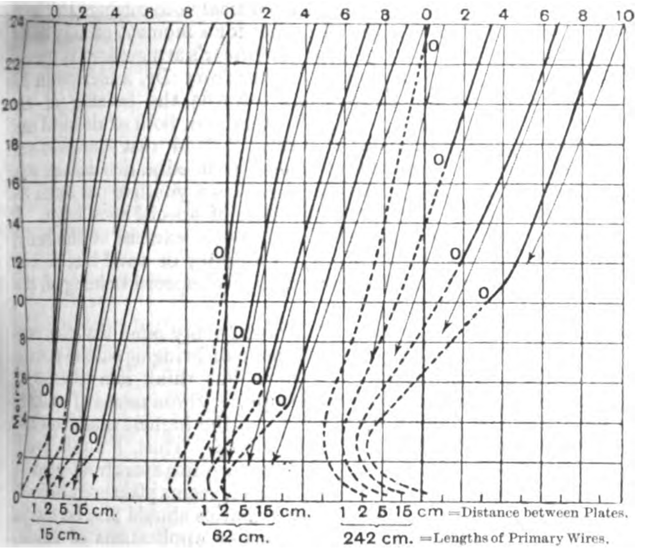

FIG. 3.—The Thick Lines represent Curves Found, the Thin Lines Curves Calculated.

with lengths of primary wires of 4, 15, 32, 62, 122, and 242cm. The results are shown graphically in Fig. 3. It was found that the condensers had the greatest effect in lengthening the waves when disposed symmetrically with respect to the exciter on the one hand and the first bridge on the other.

The wave-lengths found were compared with those given by the formula published by Salvioni,* and found to agree fairly well with their general character, as seen in the figure.

But this formula, like that published by Cohn and Heerwagen, gives only the nodes of the fundamental system. It is easily seen from Fig. 2 that the superior systems are not "harmonics" of the fundamental system in the acoustical sense, as the nodal lines do not meet in a point. Signor Mazzotto inclines to the view that these wave systems are the harmonics of the system comprised between the spark-gap and the first bridge.

THE JUNIOR ENGINEERING SOCIETY.

PRESIDENTIAL ADDRESS.†

BY JOHN WOLFE BARRY, ESQ., VICE-PRESIDENT INST.C.E.

I have been somewhat perplexed in the choice of a subject on which to speak to you this evening, bearing in mind the eloquent and instructive addresses with which my predecessors have inaugurated their various terms of office. These addresses have ranged from specific subjects of practice to the education of an engineer. I at length decided to devote myself to the subject of engineering considered generally as a calling or profession, including a few words on the subject of education for it. I propose to add a retrospect of what has been done by us engineers during my own memory, and some slight forecast of the future of the profession, in which last division those whom I have the honour and pleasure of addressing are more interested than the speaker can be.

First, then, what is the profession of civil engineering? The founders of the Institution of Civil Engineers well defined it as being the art of directing the great sources of power in nature for the use and convenience of man; and this surely is not only true now, but has been abundantly shown to be justified by the history of the years which have elapsed since the year 1828, when the words were inscribed in the Royal Charter of the Institution. The Chancellor of the Duchy of Lancaster, Mr. Bryce, in an after-dinner speech lately, humorously said that he had observed in modern novels, whereas the villain is usually a baronet, that the virtuous and clever man is almost invariably an engineer. This is putting the matter somewhat broadly, whether for the baronets or engineers, but it amusingly illustrates my thesis that our profession is one which gives scope for great characteristics, both moral and mental. Seriously, then, let us consider this question further and we shall see that among the moral qualities which engineering demands we should certainly number courage or bravery, constancy, loyalty and uprightness. I am sure that we can point to many examples of these within the recent history of our profession no less than in the past. With regard to courage, what finer examples of gallantry can we point to in any profession than that of the engineering staff of the ill-fated ship "Victoria"; when all the rest of the ship's company were mustered on the deck of the sinking ship, the engine-room staff carried on their duties below unflinchingly, and perished, I believe, to a man, among horrors which one can scarcely realise, much less attempt to describe.

Again, how necessary to an engineer is the sentiment or quality of loyalty. Loyalty to his employers, which will enable him to give advice unpalatable to them, and often contrary to what seems to be his own interest, but which is necessary for the good of the undertaking under his charge. Loyalty again to the subordinates of his own staff, or to contractors or others, whom in his position as engineer he is bound in all honour to protect against injustice or unmerited blame. How necessary also, on the other hand, is loyalty between the juniors of an engineering staff to their chief; keeping his secrets, and obeying orders without thought of their own supposed interest; giving their help ungrudgingly and doing their very best. I am happy to think that we can all think of examples of such qualities in the career of most of our profession, and I repeat that such loyalty is an essential part of an engineer's qualifications. Uprightness is of course a necessity of any honourable man, whatever walk of life he may follow. But I think that the amount of confidence which is given to engineers is perhaps greater than in any other profession.

But apart from mere honest administration of funds, there is another form of uprightness which is a necessity for a true engineer, and this brings me to the rather thorny subject of scientific evidence. I utterly repudiate the idea that any trifling with facts, or figures, or opinions is justifiable or properly attributable to engineering witnesses as a class, or, indeed, can fairly be made an accusation against them. A barrister whose whole business and theory of life is not to attain to truth, as to win cases, may accuse scientific witnesses of obscuring truth because he finds different theories advanced on the same subject. But I venture to think that when evidence of opinion is given it is almost impossible to avoid such conflict, and that the most contradictory opinions may yet be perfectly *bonâ fide*. On what subject of science can it be said that opinion is so consolidated as to be axiomatic, so that there is no room for honest difference of opinion, and how easy it is to reach different conclusions from the same data. Indeed, if such matters were absolutely clear, no evidence could be wanted about them. I am sure we must all know numberless cases where engineers have refused to support or attack by evidence when they are not themselves convinced. But the public does not perhaps know that the solicitor, often fortified by the "opinion of counsel," then seeks for someone else whose opinion whilst being *bonâ fide* happens to suit the case which the lawyers wish to advance.

The way in which evidence is thus sought for reminds me of an old friend of mine who was fond of bitter beer with his dinner, and who was urgently ordered by his doctor not to continue to drink it. I condoled with him on the deprivation, and asked him what he would do. He replied, "I shall consult another doctor, and continue to do so until I find one who recommends me my favourite beverage." I do not know whether he succeeded in finding a doctor to his mind; but if he did, it would be scarcely fair to say that either the doctor who thought beer to be harmful, or he who thought it beneficial, were one or other guilty of falsehood. Scientific testimony, then, being largely the expression of opinion, must be frequently, indeed one may almost say generally, contradictory; but that is no reason why it may not be perfectly

† Delivered November 10, 1893.

Digitized by Google

honest, and it is absurd to rail against it, because on any specific subject it may point in different directions. Such being the views I take of the subject, I may say that I consider that engineers should devote the greatest care to any matter on which they may be called on to give evidence, so as to make certain of their facts, and that they should endeavour to form their opinion upon the facts without advocacy of any particular view. I look upon giving evidence as a very serious responsibility, and it is a hundred times better to refuse to appear as a witness than to allow oneself to drift into the position of supporting views of the truth of which one is not convinced, or of twisting facts to suit a theory.

Leaving now the question of qualifications for the profession and its responsibilities, let us glance shortly at its utility as evidenced by its record for the past 50 years. Look at the improvements attained during that period in every branch of engineering. The power of locomotion by land has not so much increased in the speed of railway trains as in their weight, and in the safety and comfort of travelling. Thanks to the improvements in railway appliances, an English railway carriage is now perhaps the safest place in the world, and the percentage of accidents has fallen enormously. At present the statistics averaged for the last three years, compared with the three years 1874-75-76, are as follows :—

Passengers Killed or Injured from Causes beyond their own Control.

Average per annum.	Killed.		Injured.	
	No.	Proportion.	No.	Proportion.
For 1890-1-2......	15	1 in 56 millions	657	1 in 1,280,000
For 1874-5-6.....	47	1 in 10 millions	1,368	1 in 370,000

The number of accidents to railway *employés* in the United Kingdom (who are 381,000 in number) is still considerable, but it must be remembered that the calling is in itself one which must have attendant risks. The following are the comparative statistics :—

Employés Killed or Injured.

Average per annum.	Killed.		Injured.	
	No.	Proportion.	No.	Proportion.
For 1890-1-2.....	527	1 in 723	3,066	1 in 127
For 1874-5-6......	742	1 in 347	3,007	1 in 86

I think that these satisfactory statistics of improvement are very much due to the action of the Inspecting Officers of the Board of Trade, who from the first introduction of the block system, and of interlocking signals, took every opportunity of urging their adoption on the railway companies. The companies were for some years by no means willing to adopt these and other useful appliances ; they did not realise how much these inventions were in their own interest, not only in diminishing accidents and consequent compensation, but also in immensely increasing the carrying capacity of their lines. I believe that on the chief lines of railway not a third of the present traffic could be carried if we had not had the two inventions to which I have specially referred, the former of which has not been practically adopted for more than three years, and the latter for more than 25 or 30 years.

What achievements, again, we are proud to recall in electricity during the period under my survey. You can scarcely realise a world of only 50 years ago, which was without a telegraph, or telephone, electric light, or electric motors. We all thoroughly realise the infancy of this most attractive branch of engineering, and look forward to immense developments, considering the strides which have already been taken. Electric locomotives for underground railways are an accomplished fact, and it may well be that their use on railways generally may be largely extended. I suppose ere long that from any ordinary dwelling a telephone will be no more absent than a front door bell, and it is obvious that an immense field for improvement lies open in telegraphy. The battle between gas and electric light is, I think, already in a fair way of settlement, by which gas will remain the light for houses in which it has a value in heat, apart from light, and for domestic cooking, gas engines, and the like, and electricity will be the light of the more well-to-do houses. Our electrical brethren will perhaps scarcely admit that electricity will not hereafter supply both warmth and light, and I see no impossibility in the suggestion, though at present it seems premature.

In machinery, again, it must be difficult for you to imagine the smallness of the amount of machinery 40 years ago, and the enormous developments which have taken place in this respect in every branch of industry. The vast advantage of the single, double and triple expansion steam engines, in diminishing the consumption of coal by 50, 60 or 80 per cent., and so rendering machinery available where it was formerly unavailable, have all occurred within my memory; while the application of hydraulic power to machinery of almost every description only dates from about 1845, when Lord Armstrong—then Mr. Armstrong—had the greatest difficulty in getting his invention adopted.

This glance of mine at the progress of 40 or 50 years is merely intended as the slightest of sketches. It is not for a moment meant as a history of engineering progress, which would be far beyond the possibilities of such an address as this. But I am bold enough to ask what profession can point to such a record of progress and utility. It shows that our profession, at any rate, has been in full vigour, and it indicates also how much remains to be done. For myself, I am persuaded that there will be no halting, that the progress to which we can point is now as rapid as ever, and that the next 50 years will have as great steps to record as those of the past half-century.

I have entered on this subject, as I have said, not in the spirit of boasting for the past history of our profession, but rather to indicate its dignity and worth. As a corollary let me point out the necessity for an education which will fit men for it. One of my predecessors, Dr. William Anderson, in his Inaugural Address, entered fully on the special training which is necessary for an engineer, and I am not going over the ground which he has so occupied. He points out how indispensable a mathematical training must always be, and the special importance of modern languages, together with the necessity for knowledge of the various sciences of Chemistry, Physics, Geology, Physical Geography, Botany, and Electricity. He claims also an important place, I am glad to say, for Political Economy, on which science so many political vote-catchers are ready now-a-days to pour contempt. I do not for a moment gainsay those views of what may be said to be an engineer's armour for his special position in life, but I venture to differ from Dr. Anderson in his somewhat depreciatory expressions towards the training of the mind, which the ordinary study of literature, both of classical and modern times, most assuredly gives. I hold that education and instruction are not convertible terms ; that education means that general exercise of the mind which enables a youth to put forth his best qualities in the further acquisition of special knowledge. It is thus somewhat like gymnastics or athletic exercise of the body, which fits it for the work of, say, a military or naval life, or any calling requiring special instruction in, and special training of, the capabilities of the human frame.

If this be the correct view, it follows to my mind that the first thing in education is to use the best mode of bringing out the powers of the brain, and accordingly, I cannot but think it a mistake to despise, or even relegate to a second place, those means of making the best of a man which what we term the highest education has been found by long experience to afford. Thus, I think, every man is the better for a training in classics, quite apart from what he is to do after 18 or 20 years of age, just as it seems plain even to those who depreciate the classics that mathematics should first be taught as a general science before the particular applications of mathematics are entered upon. It is said, "Oh ! there is not time for such a course, and one must cast aside everything which one cannot see at a glance to be wanted in an engineer's career." I venture to dissent from this view, and to say that a man who has had a classical training has taken the most useful step towards not only the acquisition of all modern languages, but also of knowledge of the general literature of his own tongue, and of the special literature which he has to study for use in his profession. With respect to the various sciences I cannot but think that if a man has had a general mathematical training and has been given at school that general introduction to Chemistry, Geology, Botany, and Electricity which is now-a-days given at all good schools, the special acquisition of further knowledge of those sciences and their practical application will be better and more soundly acquired subsequently to the school age. Consider also the charms of such knowledge of the past that the study of general literature gives, and of the resource it affords for the future development of the mind during the work of life and for relaxation when leisure is available. One cannot begin these studies when once one is plunged in active business, and it appears to me that a very strong case should be made out before such advantages are lightly thrown aside. As a man who left school too early, and who had not any university training, I can truly say that I highly prize even the classical training of my old school, and such knowledge of literature that I then acquired. I only wish that it had been more, and should deeply regret if it had been less.

I think also in considering this subject we may be guided by what is done by other professions. I have already said that I hold the engineering profession as second to none, and I confess I heartily dislike the idea of our being content with one whit less of education and culture than the profession of law or medicine, or the Royal services. Let us take our proper position, and educate our young engineers thoroughly as men first, and we shall find the rest will follow. If you look at the qualifying examination for a

Digitized by Google

barrister, or physician, or surgeon, or for the army, you will find that in all cases classics and general literature is required; and why not for an engineer? I do not see that the special education of an engineer, including his practical training, or else a stay on the Continent for the acquisition of French or German, need occupy any more time than that of the other professions. Indeed, a man need not go to the Continent; a good colloquial knowledge of French or German can be attained by a young engineer without any interruption to his other work, by boarding in this country with some French or German family, of which there are so many resident in our large towns.

The Council of the Institution of Civil Engineers have of late years insisted on an examination by some public examining body of candidates for studentship, and I rejoice that they have insisted on the subject of general literature. For my part I wish that Latin or Greek had also been made obligatory. I hope as time goes on that the present qualification will rather be raised in the direction of general and classical literature, so that the curriculum of an engineer's education may be as high as that of any other profession. It may be said—"Oh, but you may keep out the poor natural or heaven-born engineer." I do not believe one word of such an argument. If a man is such a natural genius, he will not be kept back in these days of national education by any such requirements as the qualifying examination for any of the sister professions present. Again, if such a risk existed, which I deny, it is a risk which attaches to every other profession, and it had better be borne by ours as it is by others, for the general good of the profession at large. But in truth, the risk does not exist. A youth of genius, if poor, can now attain to a very high level of general education, without more than the merest pittance, or, indeed, if necessary, gratuitously, and we need not fear that an examination, which an ordinary 5th form boy at a public school can pass, will keep back the George Stephensons or Brindleys of the future, who would in our day have been in the highest standard of the Board School at 14 years of age.

I have said this much from jealousy of the position of my profession, and because I think there is a tendency which I hold to be mistaken in many leading men to take an opposite view. I have only the desire now to again refer you to what was said so admirably by Dr. Anderson on the subject of the special instruction of an engineer, bearing witness most strongly to the advantage of a training in some handicraft. In the case of a young man who is going to follow the business of a mechanical engineer, it is obvious that he must acquire an exact practical knowledge of the tools of his trade, and be thoroughly acquainted with the possibilities of the manual labour of fitters, erectors, pattern makers, moulders, and the like. This cannot, of course, be acquired in less than some three years, but in the case of an engineer who is to devote himself to works of construction, the case is different. It is not necessary for him to know intimately any manual trade, but rather to attain to a general idea of construction, and to know the value of an artisan's time. Thus for a young man as last described, I think it does not greatly matter whether it be the handicraft of a fitter who works in iron, or of a carpenter who works in wood. I confess, having been in a carpenter's shop, I have a predilection for that trade, and think that more knowledge of the principles of construction and of strains can be gained in carpentry than in other trades within the same limits of time, and that the trade of a carpenter includes within it a great deal of all other artificer's work.

Let us now glance at some aspects of the career which may lie before many of my hearers. It would be futile for any one to attempt to predict the distant, or even the near, future of engineering, but we can all see that various and numerous parts of engineering thought are at present only partially explored, and that vast fields exist for the exercise of our present or future knowledge. When we consider how very far we are at present from being able to realise the potentialities of heat, even with our most improved steam engines or gas engines, or when we think how new is the science of electricity and magnetism, we see how immense a field for investigation and adaptation is open to us in these two directions, which will affect every department of engineering. What a promising subject for improvement and extension locomotion still presents, so that enthusiastic investigators promise us railway trains at 150 miles an hour, and that road traction will soon be mainly independent of animal power. But quite apart from such fascinating anticipations of unknown developments, let us consider the more hum-drum future, and the extension of well-known works and appliances. Within the past 40 years the capital of the British railway companies has increased from 248 millions sterling in 1851 to 919 millions in 1891, or by 270 per cent. and the number of passengers from 85 millions to 845 millions, or by 900 per cent., while the mileage has only increased by 4,500 miles, or 29 per cent. In the meantime, our population has increased from 27 millions to 38 millions, a difference of 11 millions, or of 37 per cent. You will notice from the above figures that the tendency to travel far exceeds the rate of increase of population, and is also out of all proportion to the increase of railway mileage. The increase of railway capital is somewhat more proportional, but the above statistics appear to me to show what is borne out by observation, viz., that the volume of passenger traffic is continually and rapidly increasing, and that railway companies must continually add to their means of carrying it by doubling their lines, making relief lines, rebuilding their stations, and adding to their rolling stock and plant. In fact, our population and our wealth are still increasing, and this being so, there will be a constant demand for more railways, more docks, more harbours, more bridges, more roads, and the like. I can see no reason to suppose that this increase will be any less than in former years, on an average though, as heretofore there will be ups and downs.

If these be the facts about our own islands, how much greater a field also exists for engineers in India and in the Colonies with which we all hope to be more closely united, looking to a great confederation of English-speaking people in every latitude and longitude, bound together by common ties, and by mutual interests for advancement and defence. In our great Empire of India we have at present but some 17,500 miles of railway; in South Africa only about 3,000 miles; in Australia, New Zealand, and Tasmania, about 13,000 miles; and in Canada 14,000 miles. It is obvious from such figures that only the fringe of the subject of railway development has been already touched in these huge countries, while in the vast virgin fields of China, and the remainder of Africa, these problems have not even been reached. In foreign countries, also, so long as England remains the financial power in the world which it now is, and so long as English enterprise remains what it has been, English engineers will continue to be called upon to propound and superintend the various works for which English capital is provided.

Let us, therefore, have confidence and patience in the future of our calling, remembering what has occurred before, and being sure that so long as civilisation exists the civil engineer must be to the front. The progress of the future must depend very largely upon him and upon his ability to keep abreast of all knowledge of the various phases of science, and to lead the way in their application for the use and convenience of man.

ELECTRO-MAGNETIC VOLTMETERS ON ALTERNATING CURRENTS.

In a recent number of the *Elektrotechnische Zeitschrift*, M. Szapiro, of Warsaw, has an article on variations of the reading of electromagnetic instruments with the shape of the E.M.F. curve of the alternator. He works out general equations from the curves of a sinusoidal and non-sinusoidal E.M.F. for the value of the current in the two cases for given resistance and self-induction, and from the resulting formulæ deduces the following conclusions:—

1. Where the self-induction is relatively small, as in a Cardew voltmeter, the effective current, and therefore the reading, is independent of the shape of the curve of E.M.F.

2. If the resistance is relatively small, and the deviation from a sinusoidal E.M.F. curve not large, the effective current is not appreciably affected.

3. Should resistance and self-induction be of the same order of magnitude, the differences in the reading may be large for certain deviations of the E.M.F. from a sine function. Taking a concrete instance, the author takes a Ganz machine, a voltmeter of resistance = 3,000, and coefficient of self-induction = 1; then, for the same periodicity, the effective current will vary 8 per cent. from its value on a sinusoidal E.M.F. of the same effective value. These considerations, says the author, make it necessary in accurate work to calibrate the voltmeter on the alternator with which it is to be used, and not only at the right frequency.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

THURSDAY, November 23rd.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Discussion on the Paper: "The Electrical Transmission of Power from the Niagara Falls," by Prof. George Forbes, F.R.S., member.

FRIDAY, November 24th.

PHYSICAL SOCIETY.

5 p.m. (1) "The Magnetic Shielding of Concentric Spherical Shells," by Prof. A. W. Rücker, M.A., F.R.S., President.
(2) "The Action of Electromagnetic Radiation on Films containing Metallic Powders," by Prof. G. M. Minchin, M.A.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

(The Oldest Electrical Journal.)

Published every Friday, Price Fourpence: Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :
1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.
Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "THE ELECTRICIAN" Printing and Publishing Company, Limited, and be crossed "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.

"THE ELECTRICIAN" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.

New Volumes of "THE ELECTRICIAN" commence in May and November.

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months. s. d.	6 months. s. d.	12 months. s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" Printing and Publishing Company, Limited, who are proprietors of the well-known "ELECTRICIAN" SERIES of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad. "THE ELECTRICIAN" SERIES at present consists of—

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Ready January 1.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Pa C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; P William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrt Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; James Anderson; and Joseph Wilson Swan, have been issued as Sup ments to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pilla Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

NOW READY.

Volume XXXI. of "THE ELECTRICIAN," price 12/6; post free, 1 abroad carriage extra.

Cases for binding Volume XXXI., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "' ELECTRICIAN" complete except for three Nos. Price on applicati

AMERICAN ELECTRICAL ENGINEERING AND I LESSONS.

According to a correspondent of the *Daily Chronicle* PREECE has been rash enough to declare that "England nothing to learn from America in regard to electrical applianc It is unlikely that Mr. PREECE has publicly declared anyth of the kind. It is quite true that we all think somethin the sort, but we do not say it. Mr. PREECE keeps the ri side of everybody, and being essentially a public man a constant visitor to the States, would say nothing so r whatever he may think. We have, indeed, some recolle of a more or less opposite statement by him at a scien meeting. The theme of the correspondent who makes accusation is that "in America inventions are being ca out on a great scale, and with a rapidity greatly in exce Europe," and he proceeds to state briefly the facts, in o to give the English people an idea of how far behind the in the application of modern science to the needs of mo life. One of his first batch of facts relates to long-dis telephony, and calls for a remark. "At this moment prob hundreds of people in New York are talking freely and perfect distinctness in Chicago, 1,000 miles away."

Digitized by Google

suggests one of three things: either that there are "hundreds" of pairs of wires between New York and Chicago, which is, indeed, news; or that, owing to the "great scale" and "rapidity" with which inventions are applied to the needs of their modern life, some apparatus has been devised to allow four or five dozen people to talk independently on one circuit—if this is so, we have much to learn from America; or, that there is no independent talking, but that the "hundreds of people" are all chanting together in chorus, through one transmitter, the Praises of the Almighty Dollar, the Transcendant Superiority of The Nation, or some such theme on which they can all agree. No more than ten circuits were contemplated, and no definite report has reached us that more than one has been erected. We venture to suggest that, electrically, the London-Paris, or the Glasgow-Belfast telephone cables are each a "bigger thing," except in mere pounds of copper and hundreds of miles, than the New York and Chicago line.

Of course, after long-distance telephony comes electric traction, or transit, as Americans have it; and by way of a big thing the insane St. Louis and Chicago line is solemnly described as if it were on the point of completion. "The capital is practically subscribed." How often have we heard this statement about schemes which never got beyond the flaunting prospectus stage. There are big things across the Atlantic; but why should one-sixth of a long article be devoted to the glorification of a project which is less likely to come off than the "lightning express" of a certain enthusiast on this side of "the water." Then come electric street railways, as they are called. With the exception of a line in connection with the Chicago Exhibition, and one or two doubtful cases, all these so-called railways are what we call tramways. If we wish to point to real electric railways we should name the Bessbrook line, the City and South London line, and the Liverpool overhead line. These, particularly the last two, are not only essentially railways in the English sense, and have no American characteristics whatever about them, but are a long way in advance of anything that had been done in America at the time of their respective openings. Turning to electric tramways, it is said that we are far away behind our American cousins. Let us see where they are. It was the late Mr. Reckenzaun who first opened our eyes to the fact that these tramways are in many cases not started to supply a demand, but are promoted by speculators in land for the purpose of inducing builders to run up suburban residences. But let that pass; it is not possible to judge of financial results yet. Here are a few details: "It must be admitted that the addition to the immense quantity of wires which make an average city street in America look like a long vista of gigantic spiders' webs is not desirable, but there seems no other method at present quite practicable. . . . Besides the wires there are two drawbacks . . . one is the peculiar noise, . . . it is as the sound of a low hissing wind moaning along the street, and this curious sound and the humming of the perpetually moving cables is one of the lasting reminiscences of a stay in any great American city." As far as cables go, a lesson or two might perhaps be learned in Edinburgh or Birmingham, where there is no such nuisance. "The other drawback consists in the danger to life. One has to be very careful in crossing the streets at certain points. . . . I was told at Pittsburg that for several weeks two lives per day had been sacrificed on the average to the cable and electric cars. In Chicago three persons per day are killed or maimed. In many cases these are children who are playing in the streets. . . ." The *Daily Chronicle* enthusiast, then, so far forgets himself as to say that grade crossings are a disgrace to American cities, "and are permitted to disfigure and render dangerous the streets and country roads of this great land. . . ." We gather from all this that we have much indeed to learn from America, and that there are many matters which our engineers will do well to study, lest through carelessness they might make similar blunders.

Then follows the doubtful statement about Mr. Preece, and immediately after:—"America is as much ahead of England in this respect as England is ahead of Norway and Sweden." Ahead, indeed? Everyone who knows anything whatever of telephony is aware that England is indeed far behind Norway and Sweden in telephony, and is likely to be for many a year. The last confession, before a peroration of superlatives, is that "no city here that I know is so brilliantly illuminated as the City of London by night, yet electric lighting is far more general." We gather from some of these statements (passing by the confessions which quite spoil the article) that one country is very much "behind" the other. By this is meant that, as measured by the advance of civilisation, one is in a more rudimentary or savage state. We can only say that such barbarities as those described as common in America would not have been tolerated here fifty years ago when railways were introduced. These tramcars, we understand, spin along in the suburbs, where perhaps human life is still cheaper, at ten or fifteen miles an hour. We do not want "advance" of this sort, and are thankful for sensible public opinion and the firm hand of the Board of Trade to stop it. The rudimentary ideas about steam railways in America afford some excuse for such recklessness. But even Americans seem to be beginning to realise the danger. Our American correspondent called attention to the increasing number of accidents on "electric street railway lines," and to the proposed action of the city authorities at Brooklyn and at Cincinnati, in our issue of October 13th, and again this week. The American technical journals teem with accidents. A fortnight ago a shocking accident occurred at Oregon, when a tramcar with thirty passengers dashed through an open drawbridge into the river, killing, it appears, twenty-five people. Last month a flywheel burst at Brooklyn, wrecking the engine-house, stopping all the cars in the city driven from this station, and injuring three persons. Two days later the whole of the street lighting plant of Baltimore was destroyed by fire, together with plant for running 12,000 glow lamps.

But besides all this, electric lighting seems to be "in its infancy" in the United States. The flaring and spluttering arc lamps which satisfied, and in most cases still seem to satisfy, our transatlantic friends, were not tolerated over here. If it were not for the careful design and good construction of one or two thoroughly English arc lamps, arc lighting would have long ago been given up as a bad job in this country. Although we have not heard that anything new was shown at the Chicago Exhibition, this is not altogether a matter of regret; and we are glad to learn that some attention is being paid at last to sound practice rather than to novelties. The Westinghouse Company, we are informed, intend to confine themselves to good work, and this gives hope that no gigantic breakdown of their huge alternators will compete at Niagara for magnificence with the Falls themselves. Perhaps we are mistaken, and we are really behind. It is, however, difficult to find anything to learn about lighting by glow lamps from America. We are quite willing to believe there may be something, but we have not come across it. They are only just finding out in some places that the introduction of meters, where contract lighting has been in vogue, is apt to give rise to a little unpleasantness. The

Digitized by Google

main lesson that they have to teach seems to be to avoid doing anything in a hurry, and to accept nothing but really first-rate work. There may be some minor disadvantages; things may go slower and cost more. After all, it is only a matter of opinion, and it is so much more polite to be able to say that we have much indeed to learn from America.

OBITUARY.

ANTHONY RECKENZAUN.

It is with deep regret that we have to record the death of Mr. A. Reckenzaun, whose name will be long remembered in connection with electric locomotion on land and water. Mr. Reckenzaun was a well-known attendant at the meetings of scientific societies and other gatherings of electrical engineers, and his work is well known on the Continent and in America. His health had for some time past been failing, and a recent trip to Chicago did little or nothing to relieve his condition. He died on Saturday last of consumption at his home at Stockwell, at the age of 43 years. Mr. Reckenzaun was born at Graz, in Austria, where he received a thorough technical education. He had early opportunities of gaining practical experience with constructive details in the ironworks of his father, who carried out large contracts for brewery plants, tanneries, buildings, and railway material, especially for the Hungarian railways. Desirous of enlarging his knowledge he came to England in 1872, and obtained employment with the then flourishing marine engineering firm, Messrs. Ravenhill and Miller, of London, where the most powerful engines for the British and various foreign navies were constructed. When Mr. Ravenhill retired the business was transferred to Messrs. Easton and Anderson, of Erith, whither Mr. Reckenzaun followed. In connection with the Erith ironworks he established evening classes for the benefit of the *employés*, and gave lectures during three years on "Machine Construction and Drawing" and "Steam"; but, in order to qualify himself according to the rules of the South Kensington Science and Art Department, he had first to undergo the examinations in those subjects, which he passed with first-class honours. Subsequently he attended the courses of lectures given to qualified science teachers at the Royal School of Mines in 1877 and 1879, when he again obtained first class at the final examination in steam and mechanics. After visiting the Paris Exhibition of 1878 he resolved to devote himself to the study of electrical engineering, and attended Prof. Ayrton's lectures at Finsbury Technical College. In 1881, again, at the great Electrical Exhibition in Paris, he spent nearly every day for three months within the Palais d'Industrie in order to become thoroughly acquainted with all the systems then on exhibition. After his return from Paris he joined the Faure Accumulator Company, which he left, however, soon afterwards, and accepted the post of Engineer to the Electrical Power Storage Company. There he designed the first electric launch, "Electricity," driven by means of E.P.S. storage batteries, in 1882, and soon afterwards he made the electric tramcar which was exhibited on the West Metropolitan Tramway in March, 1883.

Mr. Reckenzaun delivered many lectures and read Papers on "Storage Batteries and Electric Locomotion" before scientific societies, notably the British Association, the Society of Arts, the American National Electric Light Association (when meeting in Boston, Mass.), the American Institute of Electrical Engineers, and the Vienna Electro-Technical Society. The Society of Arts awarded its silver medal for his Paper on "Electric Locomotion"; and the Institution of Electrical Engineers in December, 1892, awarded him the Paris Electrical Exhibition Premium for a Paper on "Load Diagrams and the Cost of Electric Traction." He has also written numerous articles for scientific journals, and is the author of a treatise on "Electric Traction on Railways and Tramways." He started business on his own account in 1885 for the purpose of building boats, cars, and electric motors for various purposes. The most noteworthy of the boats was the "Volta," which made the double voyage between Dover and Calais on September 13, 1886, also the more difficult voyage between London and Dover. Mr. Reckenzaun spent nearly a year in the United States, when he introduced his electric cars on several tramways, and where he built the "Magnet," the first electric launch in American waters. He was an ardent advocate of secondary batteries, and has contributed largely to our knowledge of the subject. Mr. Reckenzaun was vice-president of the Old Students' Association of the City and Guilds of London Institute; a member of the Institution of Electrical Engineers, of the Society of Arts, of the American Institute of Electrical Engineers, and of the Vienna Electro-Technical Society.

For the last few years Mr. Reckenzaun has practised as a consulting engineer, concerning himself with power distribution and accumulators. His private work for some time past has been devoted to the development of a type of accumulator for central stations. The meter which we described in *The Electrician*, Vol. XXXI., p. 8, was the invention, or joint invention, of Mr. Reckenzaun. We were not aware of this at the time, or we should, of course, have had pleasure in recording the fact.

Mr. Reckenzaun was essentially an engineer, and in devoting himself as he did to the use of accumulators for motive power, it is a question whether he did not give them more consideration than they deserved. It must be confessed that he has not lived to see any real success. Time will show whether his work will yet bear the fruit which such honest and thorough work should yield, and whether he was not in advance of his day. Accumulators are in fact at present unworthy of the labour which he expended on their application. Let this be placed on record, lest some inventor should hereafter improve the secondary battery and make it a success for locomotion, and take, or be given the credit for, the work which was so well done by Anthony Reckenzaun.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(Continued from page 493, Vol. XXXI.)

It will be apparent that the laws which govern the determination of the excitation for a given magnetic flux in continuous-current machines are equally applicable to the alternate-current designs, it being necessary, however, to modify the equation for the total electromotive force of the armature, and to arrange suitable current densities in the copper and magnetic densities in the iron. These modifications are of importance, and require elucidation. The total armature impressed electromotive force, V_{imp}, may be expressed in terms of the number of turns, the number of lines of force per pair of poles, and the number of revolutions per minute, as in the continuous-current machine in equation (6), Vol. XXX., p. 624. But since pressure is periodic, and therefore changes in value through each cycle, there will be a maximum pressure considerably greater than either the *effective* or *average* value. It is evident that both the pressure and current have all values between zero and a maximum (one positive and one negative) twice in every period, and it is therefore necessary to define what is understood by the terms alternating pressure and current.

In practice we require to know the *effective*† values, and not the maximum or instantaneous values. The readiest means of comparing the *effective* values of an alternating and direct current is afforded by the several heating effects produced in a wire of known resistance having no self-induction. When the heat caused by the current is the same in either case, then the effective pressure of the alternate current is equivalent to the continuous pressure.

Instruments which depend on the heat waste, $i^2 R$, are calibrated by continuous currents, the effective values of which are proportional to the squares of the uniform currents, and

* All rights of reproduction reserved.

† Prof. Silvanus P. Thompson prefers to use the older term, "*virtual* value.

Digitized by Google

therefore the readings of the instruments are proportional to the square root of the mean square of the currents (usually written $\sqrt{\text{mean square}}$). For example, the heat produced by a continuous current of 10 amperes is proportional to 10^2, and the readings of an ammeter of the dynamometer type placed in the circuit are proportional to $\sqrt{10^2}$. If the same instrument were placed in an alternate-current circuit and gave the same deflection, the $\sqrt{\text{mean square}}$ value of the current would be as before, 10 amperes, and this is called the *effective* strength of the alternate current. This $\sqrt{\text{mean square}}$ value is independent of the shape of the curve, which, however, determines its ratio to the maximum value.

If it be assumed that the pressure and current are harmonic functions of the periodic time, the curves of either will be sinusoidal, and may be expressed by an equation of the order—

$$y = a \sin t,$$

where y is the instantaneous value of the pressure or current, t is the time of one period (it is most conveniently reckoned in angular measure), and a is a constant numerically equal to the maximum value of y, which occurs when

$$t = \frac{\pi}{2}, \text{ for } \sin \frac{\pi}{2} = 1.$$

Fig. 74 shows a sine curve of wave-length t. The ordinates y_1 and y_2 may represent either values of pressure or current, at the corresponding instants t_1 and t_2.

The arithmetical mean value of the ordinates y_1, y_2, y_3, &c., in Fig. 74 is $\frac{2}{\pi}$ times that of the maximum ordinate; or the average value = 0·637 times the maximum value.

But the total heat generated per second in the wire is a numerical measure of half the square of the maximum ordinate of a simple periodic current; for the mean of the squares of the sine, either for one quadrant or a whole circle, is one-half of the square of the maximum value, or $\frac{i^2_{max}}{2}$. And therefore instruments depending on the estimation of the heat waste ($i^2 R$) will measure $\frac{1}{\sqrt{2}} = 0·707$ of the maximum value of a periodic current or pressure.* And the continuous current which will give the same deflection on the instrument, that is, the same heating effect, is equal to $\frac{1}{\sqrt{2}}$ times the maximum value of the alternate current.

Therefore, an alternating current, if it follow the sine law, will cause a heating effect greater than that of a continuous current of the same *average* strength by the ratio of 0·707 to 0·637, that is, about 1·1 times greater. In these pages when an alternate current or pressure is referred to, unless otherwise stated, it is assumed that effective values are understood, and that pressure measurements are made by hot wire or electrostatic voltmeters, and currents are read by dynamometers. The *effective* value of the total armature electromotive force may be written

$$V_e = k\, N_a\, C_a\, p\, \frac{n}{60}\, 10^{-8} \quad . \; . \; . \; . \quad (26)$$

if all the coils are in two parallels, or

$$V_e = 2k\, N_a\, C_a\, p\, \frac{n}{60}\, 10^{-8} \quad . \; . \; . \; . \quad (27)$$

if they are in one series.

The symbol V_e = the effective pressure in volts,
p = the number of pairs of poles,
n = the number of revolutions per minute,
N_a = the magnetic flux from one pair of poles,
$C_a = 2\,p\,w$, where w = the number of active conductors on one side of one coil; or, briefly, C_a = the number of turns counted all round.

The symbol k requires special explanation.

The quantity expressed by k is a constant for the particular arrangement of pole-pieces and armature coils; it is the ratio between the effective and the average pressures. If the pressure curves obey a sine law—it does very nearly in many types of alternators—$k = 1·1$, and this value may be taken in most rough approximations. The equations for the electromotive forces of alternators, assuming a *sine law* is followed, may be written thus:—

Two parallels: average total volts $= N_a C_a p \frac{n}{60} 10^{-8}$ . . (28)

One series: „ „ „ $= 2\, N_a C_a p \frac{n}{60} 10^{-8}$. (29)

Two parallels: maximum „ „ $= \frac{\pi}{2} N_a C_a p \frac{n}{60} 10^{-8}$. . (30)

One series: „ „ „ $= \pi\, N_a C_a p \frac{n}{60} 10^{-8}$. . (31)

Two parallels: effective „ „ $= \frac{\pi}{2\sqrt{2}} N_a C_a p \frac{n}{60} 10^{-8}$ (32)

One series: „ „ „ $= \frac{\pi}{\sqrt{2}} N_a C_a p \frac{n}{60} 10^{-8}$ (33)

The numerical value of the constant in equation (32) is approximately 1·1. In equation (33) for series coupling the coefficient must be twice as great as that in equation (32), if the same value of C_a be retained, and it is therefore equal to $2 \times 1·1 = 2·2$. In practice it is found to vary between 2·2 and 2·3 when the coils are all in series.

The pitch of the pole-pieces and the width of the armature cores are of great importance in designing alternators, for they affect the shape of the pressure curve, and consequently the effective pressure and the output. Four of the more frequent arrangements are illustrated in Figs. 75, 76, 77 and 78, which it will be necessary to examine carefully before proceeding with the calculation of the output. In these diagrams the field poles are developed horizontally, and the polarity is indicated by capital letters. The winding and bare spaces on the armatures and the apertures of the coils are clearly marked. The pitch of the field poles is equal to half of a wave length, and, therefore, in Figs. 75, 76 and 78, it is equal to the angular width of one pole and one space; whilst in Fig. 77 (which refers to the Brush Alternator) it is equal to that of one pole only, for there the spaces, strictly speaking, act as if they were poles of opposite sign to those hatched in the diagram. It will be noticed in this case that the armature coils are twice as numerous as the field poles.

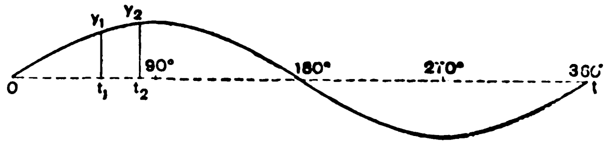

Fig. 74.

Below each figure is the theoretical shape of the pressure curve in full lines, determined on the assumption that there is no magnetic leakage between the poles, and that therefore there is no fringe at the corners of the pole-pieces. This is not the case in practice, and therefore the actual curve will be less angular, and approximate more or less closely to sine curves, as shown in dotted lines. This is easily seen to be the case with Figs. 75 and 76, and practically it is found that the design in Fig. 77 gives an almost perfect sine curve. In tracing the pressure curve for any arrangement of pitch and angular width of poles and coils the zero points may be first determined and marked off on the line $a\,b$, which shows the angular position of the coils. Having found these points the wave-length is known, and the positions of maximum pressure should lie midway between the zero points. If the *winding spaces* are exactly equal to the *width of the poles*, then, assuming no magnetic fringe, the intermediate values lie in straight lines, joining the maximum and zero points as in Figs. 75 and 78. The height of the maximum ordinate depends on the scale selected, but its numerical value can be found from the known magnetic flux and the linear speed of the coils. In these diagrams an arbitrary height has been selected. If the coils be in one series, and a simple zigzag curve be assumed, then

$$V_{max} = 4\, C_a\, N_a\, p\, \frac{n}{60}\, 10^{-8} \text{ volts}, \quad . \; . \; . \quad (34)$$

* For a more complete explanation of the interesting phenomena of alternate currents reference should be made to "The Alternate Current Transformer (in Theory and Practice)," by Prof. J. A. Fleming.

Digitized by Google

where the maximum pressure is assumed to be twice the average pressure. If the winding space be shorter than the polar width, then the maximum pressure will be maintained for that

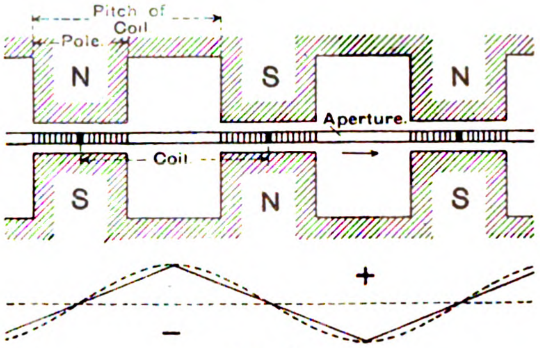

Fig. 75.

period of time during which the coil as a whole is passing under the pole piece. Thus, if the polar arc be 10in. in

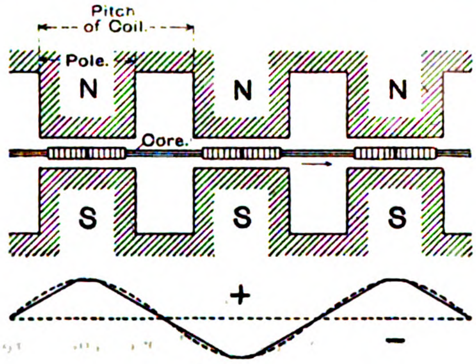

Fig. 76.

width and the winding space only 8in., then for the fraction of time required for the coil to move through the angular distance of $10-8=2$in., the pressure will have the same

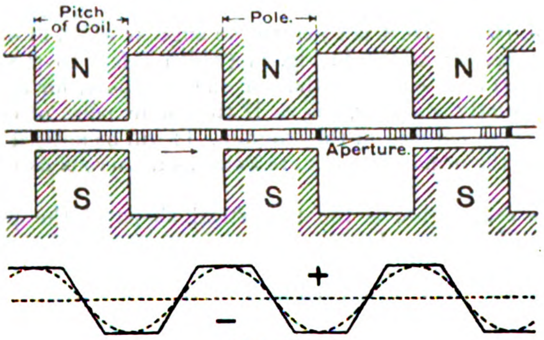

Fig. 77.

value, and hence the top of the crest will be flat, as in Fig. 76, which refers approximately to the design of the Kapp alternator.

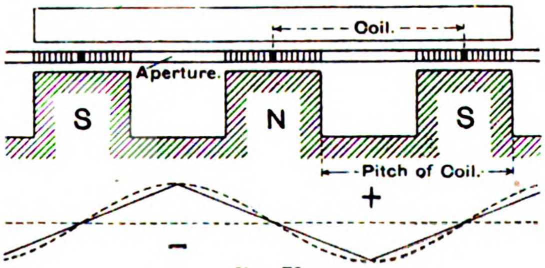

Fig. 78.

In some designs the coils are made to exceed the poles in width by a small percentage, the arrangement being found to give a very close approximation to a sine curve. Prof. Thomson, of the Thomson-Houston Company, is in favour of such proportions.

The Gülcher alternator, designed by Mr. W. B. Esson, also embodies this idea, but the armature coils are only half as numerous as the field poles, and are equal to the width of three and a-half poles. There is a distance piece between the coils equal to half of a pole, the pole being of the same width as the space (*see* Fig. 79). The theoretical curve of pressure is shown in full lines, and a sine curve is indicated by a dotted line. It is evident that this arrangement approximates very closely indeed to the necessary conditions for obtaining a sine function.

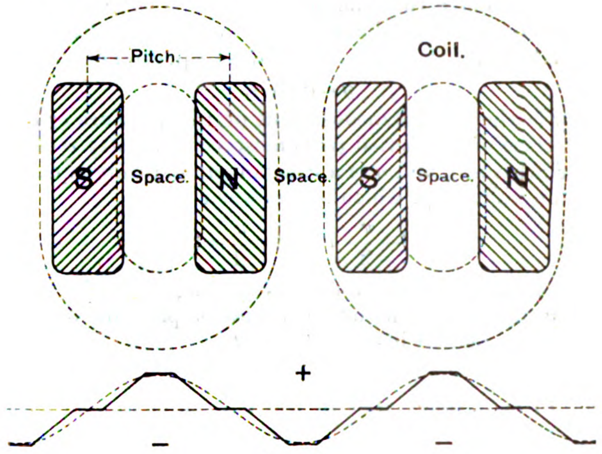

Fig. 79.

The curve of pressure of any arrangement of pole-pieces and armature coils can be traced approximately, and then it is easy to determine the effective pressure with sufficient accuracy for practical purposes. Consider the curve in Fig. 80, the half wave length is equal to, say O X, and V_{max} equals the maximum ordinate. Now, bearing in mind that the instruments used for measuring alternate currents give readings proportional to the $\sqrt{\text{mean-square}}$, it is necessary to square the ordinates

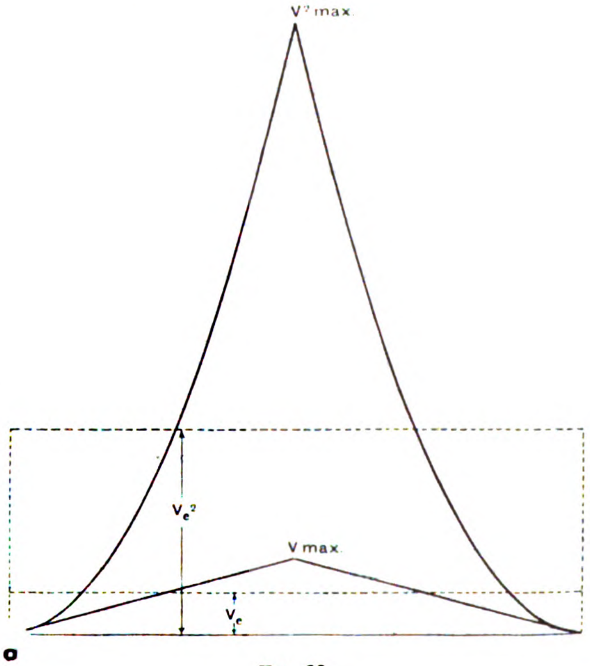

Fig. 80

of O V X and plot a new curve on the same base and then to find the mean ordinate, say V_e^2, of the squares. This can be readily found for most symmetrical figures by integration; but many engineers prefer the graphical method, which is as follows:—Plot the curve to any convenient scale on squared paper and divide the base line O X into any number of equal parts—the more the better. Measure the heights of the

ordinates at the middle of each and divide the sum of their values by the number of parts: the result is the numerical value of the mean square, V_e^2 in the selected units. Next extract the square root and then the effective pressure V_e, is known. This has been done in Fig. 80, for the triangular pressure curve $O\,V_{max}\,X$, and the value of V_e is found to be 0·58 of the maximum pressure ; or

$$V_e = 0{\cdot}58\ V_{max}.$$

In Fig. 81 the same operation has been performed for a semicircular curve, and it is found that

$$V_e = 0{\cdot}7854\ V_{max}.$$

Thus equation (34), which gives the value of the maximum pressure, must be multiplied by 0·58 to equal the effective pressure. Therefore, if the coils be in one series, since

$$V_{max} = 4\ C_a\ N_a\ p\ \frac{n}{60}\ 10^{-8},$$

$$V_e = 0{\cdot}58 \times 4\ C_a\ p\ N_a\ \frac{n}{60}\ 10^{-8}$$

$$= 2{\cdot}32\ C_a\ N_a\ p\ \frac{n}{60}\ 10^{-8}. \quad . \quad . \quad . \quad . \quad (35)$$

And if the coils be coupled in two parallels, then the effective pressure is half as great as the value given by (35).

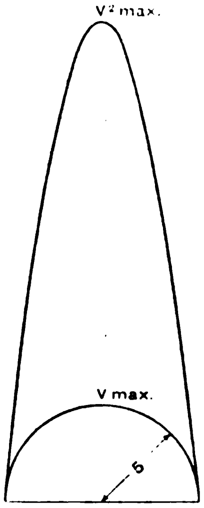

Fig. 81.

The relation between the effective and average values for the more common curves, and the theoretical values of k, are shown in Table J :—

Table J.

Order of curve.	Average value as a decimal of the max. ordinate.	Effective value as a decimal of the max. ordinate.	k = Ratio of effective to average average.
Sine	0·637	0·707	1·1
Semicircle.....................	0·7854	0·835	1·063
Triangle	0·5	0·58	1·16
Rectangle.......................	1·0	1·0	1·0

The above values of k will not be realised in practice, since the magnetic fringe will cause the angles to be rounded. The shape of the curves will also be largely affected by the pitch ratio of the poles and coils.

There is some difficulty in finding the actual value of k in practice, since the exact magnetic density B_a is not easily found without special experimenting. The designer, of course, knows the calculated value of N_a, and consequently B_a, and then from the measured pressure may calculate k with a fair degree of approximation to the truth. But if a small test coil be arranged so as to explain the gap at various places, then the average value of N_a may be readily found ; this, however, is not an easy thing to do in an ordinary shop with workshop instruments with the pressure of commercial routine.

Mr. Kapp has made a special study of the coefficient k, and the following table is based on his researches. The windings are assumed to be in one series, and the width of the poles and coils is expressed in decimals of the pitch.

Table K.—*Proportions of Field-Poles and Armature Coils in Terms of the Pitch, and Consequent Values of k.*

Ref. No.	Pitch.	Pole.	Total breadth of copper in each coil.	$2k$.
1	1	1	1 (covering whole surface)	1·16
2	1	1	0·5 (covering half surface)	1·635
3	1	0·5	1 (covering whole surface)	1·635
4	1	0·62	0·5 (covering half surface)	2·06
5	1	0·5	0·5 (covering half surface)	2·30
6	1	0·33	0·33 (covering third of surface)	2·832
7		Sine Function		2·22

Nos. 4 and 5 approach most nearly to designs found in practical machines.

Having thus determined the total effective pressure of the alternator, it is easy to find the terminal effective pressure.

This will be given as for continuous currents by equation (5). Thus, if v_e be the effective terminal pressure, then

$$v_e = V_e \pm i\,r,$$

where i is the current in the armature and r the resistance of the coils.

(To be continued.)

ELECTRIC LIGHTING AT GABLONZ.

A good deal of attention is paid on the Continent to the subject of the utilisation of water power for driving dynamos, and a somewhat exceptional plant exists at Gablonz, one of the chief industrial towns of Bohemia, inasmuch as the water power is used in the day-time for industrial purposes, and at night for electric lighting.

This plant, which is due to the enterprise of some local manufacturing firms, has been carried out under the direction of Messrs. Kremenezky, Mayer and Co. Power is derived from the River Neisse. There is a fall of about 75ft., the turbine developing about 200 H.P., and in addition there is a 500-H.P. compound steam engine. There are seven dynamos in the machine room, of which four are used for public lighting and the rest for the works of Mr. Hoffmann, the originator of the scheme. They run at 530 revolutions per minute, and furnish current either at 180 volts and 185 amperes, or at 260 volts and 108 amperes. The dynamos are of the Manchester type. Although this plant is at present sufficient for the demand, it has been considered advisable to have reserve power, which is drawn from another part of the Neisse, where a fall of about 50ft. is available. The new turbine will give about 200 H.P., and will be used for driving two dynamos, each of 35 kilowatts. The current from the dynamos is lead to a general switchboard in the machinery room. Current is taken from the generating station in the outskirts of the town to the accumulator station in the centre of the town by means of an underground cable of 200 square millimetres section of copper. There were originally two batteries, each of 86 Tudor cells, possessing a capacity of 630 ampere hours, from which current is distributed on the three-wire system. There has now been added a 172-cell battery of a capacity of 790 ampere hours. The most of the distribution is carried out by underground cables, though there are some overhead wires to outlying districts, the town being built in a very straggling fashion. In addition to private lighting, the plant supplies current to some arc lamps for street lighting. Among the public buildings lighted is the synagogue and the infirmary, the latter having also a pump driven electrically. The current has been found of much utility in connection with the supply of power. Many of the export houses of the town use it for driving their lifts, and it is also employed for lathes and other machinery.

ELECTRIC LAUNCHES AT CHICAGO.

The following analysis, for which we are indebted to the *Electrical Engineer* of New York, showing the costs of running the electric launches at Chicago, may interest our readers :—

APRIL 13TH TO OCTOBER 1, 1893.

Mileage and Passenger Traffic

Passenger trips of three miles each	47,787
World's Fair special launch trips	6,750
Special trips of regular launches	1,220
Trial trips	270
Experimental trips	180
Total number of trips	56,207
At three miles per trip, total miles	168,621
Average miles per launch to Oct. 1st	3,122
The total number of days the 54 electric launches have been in service on the lagoons of the World's Fair, is	6,594
Therefore, the general average of miles per launch, per day, is ...	25·57
Minimum miles, per launch, per day	14
Maximum „ „ „	37½
Maximum miles, one launch, one day	54
Total number of passengers carried from May 1st to October 1st.	801,0C0
Maximum passengers carried in one day by one launch	464
Maximum number of people carried by one launch for one round trip	40

Operating Cost.

Average cost per launch per day for charging, at 3 cents per electric horse-power hour	55½c.
Average cost per launch per day for care and repair of shafting, propellers, 54 motors, 162 packing-boxes, 3,524 storage batteries, including labour for charging, 54 controllers—all the above being gone over every 24 hours	43c.
Renewals of batteries per launch per day	41c.
Renewals and repair material for all else per launch per day	9c.
Total cost per launch per day	$14. 8½
Average cost per launch mile for labour and material, exclusive of office expenses	5⅞c.

INSTITUTION OF ELECTRICAL ENGINEERS.

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.*

Introductory.

I had originally intended the title of this Paper to be "The Transmission of Power by Electricity," but I found on writing it that it was inevitable that the work on which I am engaged as electrical consulting engineer at Niagara Falls should take a very prominent part in its substance ; but the Paper does still deal with the general question.

On December 14, 1892, I read before the Society of Arts a Paper on the utilisation of Niagara Falls, in which the general plan of operations was described. But at that time the electrical developments were not sufficiently advanced to enable me to treat of that part of the subject. A reference to that Paper will prevent the necessity of my wasting time and describing in detail the civil engineering and hydraulic arrangements. The object of the present Paper is to put before this Institution the circumstances under which this great problem has been attacked, and the views which have been arrived at, and also to describe, so far as any work has been done, the electrical machinery to be installed.

The utilisation of the Falls of Niagara has long been a favourite theme of engineers, but it was not until the transfer of power by electricity became feasible that this could enter very satisfactorily into the region of practical engineering. The matter is now in the hands of one of the most powerful combinations of New York capitalists which has ever been formed. Under their auspices the matter was, for the first time, thoroughly investigated from an engineering, financial, and commercial point of view. Rights were then acquired, and companies formed. The Cataract Construction Company does the engineering work, and will then hand it over to the Niagara Falls Power Company. The Land Development Company builds a whole village on the extensive lands acquired. The Niagara Junction Railway Company constructs six miles of terminal railway to connect all the factories, as they are built, with the railways in the neighbourhood. Rights of way are obtained in many directions, and also over the Erie Canal, which connects the Niagara and Hudson Rivers. Allied companies are formed to develop power to all the cities within reach. Roads are made, leases of land granted, factories built, and the engineering works taken in hand by the Cataract Construction Company. It is with this latter that we have chiefly to deal. Mr. E. D. Adams is the president, Mr. F. L. Stetson the first vice-president, and Mr. E. A. Wickes second vice-president ; Mr. W. B. Rankine is secretary and treasurer ; Mr. G. B. Burbank is the chief engineer ; and Dr. Coleman Sellers acts both as consulting engineer to the Cataract Construction Company and president of the Niagara Falls Power Company, while undertaking at the same time many of the duties of resident engineer. The waters from the river are taken in at a point about a mile and a-half above the Falls by a canal, from which it is led, by channels, into a long slot in the ground, going to the depth of 200ft. In this slot are iron pipes, or flumes, down which the water is carried to the turbines, and the waste water is carried through a tunnel for a distance of 7,000ft. to a point a few hundred yards below the American Falls, where it discharges into the lower river. Each turbine is of 5,000 H.P., revolves at a speed of 250 revolutions per minute, and is mounted on a vertical shaft. Above it there is a shaft extending in a vertical direction to the surface of the ground, on which a power house is built, and the revolving part of the dynamo is placed directly upon the top of this shaft. The present Paper may be divided into two distinct parts—first, the plans of working, of which, as their consulting electrical engineer, I have recommended the adoption ; and, second, the design of the machinery which is to be used. In neither of these two parts can I claim to have done anything of great novelty or originality. I have simply collected together the results of experience which are available to all engineers, and in any advice that I have given I have simply followed the logical conclusions that were to be derived from the past experience ; and in this I have been benefited by the courtesy and kind assistance of professional men, inventors, and manufacturers in both continents, who, almost without exception, have put their experiences at my disposal. If I have been the instrument to put before the Company any designs of value, it has been to a great extent as the assembler of ideas which have originated as often in the minds of the engineers and draughtsmen who have given me their assistance, as in my own. I wish especially to express how much the Company is indebted to Prof. Coleman Sellers, one of the most distinguished mechanical engineers in the United States, and who has assisted me throughout with his advice and suggestions, and who may be said to have originated the form of bearings and their supports which are to be used in the Niagara dynamos. I have also received valuable suggestions from my colleagues, Prof. Unwin and Colonel Turrettini, and also from the draughtsmen who have assisted me, and from numerous friends in our profession.* I have been desired by the President of the Company to take this opportunity of stating some of the events which have culminated in the present satisfactory position of the Company with regard to its contracts for machinery.

Relative Advantages of Direct and Alternating Currents.

A few years ago it would have been considered necessary to devote a considerable amount of space to the discussion of the relative merits of direct and alternating currents. During the last two years, however, opinions have advanced so steadily in the direction of preferring the alternating current for the transfer of power to any considerable distance, that it is not necessary to give much time to this question. One of the chief difficulties in connection with using the direct current is that it is necessary for getting the best results, to connect a number of dynamos in series, and also to put the motors at the receiving end in series with each other. This involves the insulation of each dynamo and motor from the earth—a requirement which can in some cases be attained, but which in a general system of distribution is apt to be attended with difficulty, and perhaps with danger. The best case of the kind which has been put in practice is that of Genoa, and we gave it the most serious attention, but came to the conclusion that, for our purpose, it was undesirable.

The facility which the stationary transformers used with the alternating current give for varying the pressure according to the requirements of economy or safety, is one great feature in favour of the alternating current. The question was considered in all its bearings with the utmost care, and it was not until the month of May, 1893, that the Board of Directors passed the resolution to adopt the alternating current both for their distant transmission and also for the works nearer to the power house. It was proposed, indeed, by some manufacturers to distribute the current within a radius of a mile or two at 700 or 800 volts, and one firm proposed to do this by means of a direct current. Had this plan been accepted, we should have arrived at the surprising result that

* Paper read by Prof. George Forbes, November 9, 1893.

* I must mention the names of the following draughtsmen who have worked on the dynamo designs for me. In England, Mr. F. M. Weymouth was chief draughtsman, assisted by Messrs. A. Wilson, R. H. Simpson, G. E. Groom, F. Willby, W. L. Hamilton, W. M. Williams, and W. H. Hudson. In America, Mr. Baumann was chief draughtsman, assisted by Messrs. Steen and Jacobson ; Mr. Vogel also worked for me there.

Digitized by Google

by using the continuous current at 700 volts within a mile or two, and high-pressure alternating current for more distant places, it would have cost more to produce a horse-power per annum at Niagara Falls than at Buffalo.

The argument that seemed to me the most important in favour of using the direct current was, that motors for this purpose have been made in much larger quantities than alternators, and that it would be seldom necessary to build special types of machines to act as motors. This advantage seemed to be of great importance, until I realised the value of a low frequency used with the alternating current. So soon as we reduce the frequency low enough, we are able to alter a direct-current motor into a synchronising alternating motor, by the simple addition of a couple of rings placed on the commutator and electrically connected with opposite bars of the commutator, and a brush rubbing on each of these collecting rings. I also took into consideration the question of the possibility of storing up energy in storage batteries during the night-time, when, of course, the demands on our plant would be least, and giving it off during the daytime; but at the present time the cost of the batteries would not repay work in this direction, and it would be cheaper to make another tunnel, with wheel pits, turbines, and all the paraphernalia required to generate current, than to go to the expense of putting down the large amount of lead which is required for these batteries. With the alternating current we have the choice of a considerable number of motors of different types. We have the synchronising motor, the series-wound motor with laminated field and commutator, the multiphase motors, which attracted so much attention at the Frankfort Exhibition of 1891, and a host of single-phase motors which have been developed by various inventors, but which have never been placed on the market because of the high frequency which has been prevalent, and with which they were not altogether satisfied. These motors become immediately available if we use a lower frequency. The generation of an alternating current also permits of the use of a commutator, or rectifier, with direct-current motors.

Number of Phases.

Assuming now that it is generally agreed that the alternating current must be adopted, not only for the distant transmission, but also for the nearer work, the next point to consider is the number of phases—whether the current should be generated in a single phase, in two phases, or in three phases. The possibility, too, of using even a greater number of phases was also considered, but it did not seem to possess advantages.

As already stated, there are many motors which are suitable for use with a single phase at low frequency, and which start without assistance. In the workshops of nearly all the most able electricians which I have visited in the course of the last year or two I have found such motors built upon different plans, and nearly all of them seemed to work fairly well, and promise to be very efficient at low frequency.

For all heavy work, which is going on constantly without stopping the machinery, no motor could be more suitable than the synchronising alternator on a single phase, and its speed is as regular as that of the turbine which is developing the power. It seems, however, that even if single-phase motors are going to be adopted it would be best for the generator to have two phases, because in this way we get a larger output for the same size and price of machine: the circuits may be perfectly independent, and supply separate motors. Also, the two-phase system makes the rectification or commutation of the current more easy to use it for street railways, electro-metallurgy, &c. Again, multiphase motors have a great advantage that they have been considerably utilised already, and even in small sizes have a fairly good efficiency.

With regard to the relative merits of two and three phases, several claims that cannot be supported have been put forward in favour of the latter. First, it is claimed that the saving in the copper on the line is 25 per cent. over a one-phase system, and 25 or 13 per cent. over a two-phase system, according as four or three wires are used for the purpose. I investigated this matter carefully, and arrived at the conclusion that this was not the case, and that the three-phase system had no advantage in this respect over a two-phase system with three wires. Second, it is claimed that there is a greater simplicity of wiring with three phases than with two phases; but this advantage disappears when we remember that the two-phase system can be used with only three wires, although this is not a plan which I would recommend. Third, it is claimed that any pair of the three wires may be used for a distribution of lighting. This is not the case. A two-phase system, where the circuits are completely independent, is much more suitable for the purpose, and maintains the lights at a more constant electric pressure. Fourth, it is claimed that there is a smoother starting and rotating effort with the three-phase than with the two-phase system. This was originally claimed on theoretical reasons only by Dobrowolski, but everyone who has used the type of two or three-phase motors made by the Oerlikon Company, by C. E. L. Brown, and by the Allgemeine Electricitäts Gesellschaft, of Berlin, and others, is convinced that this advantage, which seems probable enough, is purely theoretical; it is not confirmed by actual practice, and, moreover, when the fact is known, the theoretical reason is pretty evident.

No other claims in favour of the three-phase system over the two-phase have ever, to my knowledge, been advanced; and, as shown above, a very full consideration of these claims does not tell in favour of the three-phase.

I will now point out what seemed to me great objections against the three phases, due to the fact that the three conductors are all inter-connected. First, it introduces trouble in maintaining the efficient working of the line, and in testing it; so that a higher type of electrician would be required to make these tests, and even he would have greater difficulty in finding the faults and correcting them. Secondly, when the three circuits are unequally loaded, the electric pressure varies considerably. These difficulties have been thoroughly appreciated by workers in this line. When an inter connected set of circuits such as the three-phase system employs is used, it is found that when the circuits are unequally loaded there are great variations in the electric pressure, and the following tests were made at my request to illustrate this. The three circuits are called A, B, and C. The average electric pressure of the three branches at the terminals of the secondaries was maintained constant. A resistance tending to reduce the electric pressure at the lamps 5·3 per cent. was introduced into each branch. Both the primaries and the secondaries were connected as represented by the form of the letter Y. By varying the connections in different ways, some slight variations were possible; but this general fact remained—that when A is loaded and B and C are not loaded, the pressure of A is less than that of C, and that of C is less than that of B, and the difference may be 12 or 13 per cent.; and when A and B are loaded and C is not loaded, the pressure of A is less than that of B, and that of B is less than that of C. The variations here shown in the pressure of two equally loaded circuits is probably due to the armature reactions, and would be found in a two-phase system also; but the rest of the variation is due to the inter-connection of the three circuits, and is an obvious defect of the three-phase system. In order to get over this difficulty, the Oerlikon Company proposed to devote only one circuit to lighting purposes, which shall be maintained at constant pressure, using the other two circuits for power purposes, where constancy of pressure is not so important. In some cases this would be a suitable method of working, but it was not considered satisfactory for the work at Niagara Falls. Having considered these points, the Board of Directors of the Cataract Construction Company, at their meeting in May, 1893, determined to reject the three-phase system, leaving the single-phase and the two-phase available.

Frequency of Alternations.

I wish now to say some words on a question which has absorbed my most serious attention, especially since I have been acting for the Cataract Construction Company, and this relates to the frequency of the alternating current. In America a frequency has generally been adopted of 133 complete periods per second for lighting purposes. This was done with the object of reducing the cost of transformers, which were supplied to each separate house, and consequently were always of small size, and therefore expensive. The selection was also approved because American engineers working with alternating currents have generally put forward the view that parallel work is not desirable, and the fact that parallel working is more difficult at high frequency, which is one of the principal objections to high frequency, has not been seriously considered in America. In Europe the usual frequencies are from 70 to 100 periods per second, but a notable exception exists in the case of Messrs. Ganz and Co., of Buda-Pesth, who have adopted 42 periods per second. Some years ago I unwittingly did Messrs. Ganz the injustice to say that I thought it probable that they had adopted this frequency because it suited their particular

Digitized by Google

type of machinery and speed of running. I have it in writing from them, and I am thoroughly convinced of the truth of it, that their reason for adopting the frequency of 42 periods per second was that it is the lowest frequency that is available with arc lights so as not to produce any serious flickering, and their desire was to lower the frequency as far as practicable in order to ensure parallel working. Of course it is a matter of common knowledge that parallel working is assisted by lowering the frequency.

With the large units which will be employed in connection with the Niagara Falls scheme, the cost of the transformers is very much diminished; and this does not become so important a matter as it does when all the transformers are of small size—under 10 H.P., as is usual in electric lighting in America. Moreover, although with lower frequency the transformers must be increased in size, the increased cost is not in proportion to the lowering in frequency, because we can use a higher induction. Mr. Steinmetz has shown that the loss due to hysteresis varies as the induction raised to the power 1·6, and it is this loss which must be kept constant when we vary the frequency. I deduce from this law the fact that in any transformer, if the hysteresis loss is kept constant, its power of doing work varies in proportion to the frequency raised to the power 0·4 (but it is probably unwise to increase the induction so much as to saturate the iron). It follows that when we double the frequency we get out of the same transformer 132 units of work instead of 100. If the frequency were quadrupled we should get 174 units instead of 100. I have been informed by Mr. William Stanley, jun., of Pittsfield (Mass.), that without the use of theory, but simply working from his experience in manufacturing and testing transformers, he obtains almost identically the same law; and I have got independent practical testimony in the same direction from other manufacturers. It appears, then, that there can be no doubt that in lowering the frequency we are not proportionately increasing the cost; but at the same time it must be realised that the cost of transformers is to a certain extent increased by lowering the frequency. If the frequency be reduced to one-half, the cost is increased about 50 per cent. The lowest price which has been quoted for large transformers is 3·52 dollars per H.P., at a frequency of 42 periods per second. In halving the frequency the extra cost would therefore only be 1·76 dollars per H.P. It becomes, then, a matter of inquiry whether the benefits to be derived by lowering the frequency in such a proportion would compensate for the extra expenditure as indicated. I am thoroughly convinced that the gain is far in excess of this amount. I shall have occasion to discuss the superior efficiency of motors at low frequency; and in most types of motors I think it safe to say that in passing from 42 periods to 21 periods, or varying the frequency in that proportion, we have a gain of at least 3 per cent. in the efficiency of the motors. Neglecting altogether the increased value of the motors from this cause, there is 3 per cent. more power at our disposal, which, at only 10 dollars per H.P. per annum, would amount to 30 cents per annum, or, capitalised at 5 per cent. represents an increased value of 6 dollars per H.P. of the plant, against which we have the increased cost of transformers—only 1·76 dollars. It appears, then, pretty certain that, from a purely economical consideration of the question, a lower frequency than any which has hitherto been adopted is advantageous.

With regard to the lowest limits at which we can work, since our turbines have been designed to revolve at 250 revolutions per minute, a two-poled dynamo—if such could be satisfactorily constructed—would give a frequency of $4\frac{1}{6}$th periods per second, and none of the synchronising or polyphase motors employed at different factories could run at a higher speed than 250 revolutions. I am not sure that it is desirable that any motors should run at a higher speed than this, but in the few cases where this might be desirable the use of belts would be quite natural in order to give the higher speed. With a four-poled machine we would have a choice of speeds at 500 revolutions, 250 revolutions, and any submultiple of these speeds, for by increasing the number of poles in the motor the speed of the motor can be reduced as much as we please. With eight poles in the generator the maximum speed is 1,000 revolutions per minute, which is as high a speed as would generally be desired in connection with the factories supplied from Niagara Falls. This frequency is $16\frac{2}{3}$ periods per second; and after considering the three points—namely, cost of transformers, speed of synchronising motors, and convenience in the design of the generators—I came to the conclusion that, so far as motive power was concerned, this is the frequency which would be most favourable for use at Niagara Falls.

Another indirect advantage of using a low frequency is of a very practical nature, and lies in the fact that the ordinary continuous-current dynamos of any size that are made may be used as synchronising motors by means of rings attached to the commutator bars in the manner which has been above described. This method of altering and working a direct-current motor so as to make it suitable for an alternating current of low frequency has long been known to electricians, but the attention of those who are not experts was forcibly directed to it by the machines shown by Mr. Schuckert and others at the Frankfort Exhibition in 1891. Owing to this fact, it would be possible for any manufacturer connected with our supply station to procure a motor of low frequency of any moderate power he might require at a day's notice; and this is not true of any other alternating motor, nor is it true of a higher frequency.

(*To be continued.*)

ROYAL METEOROLOGICAL SOCIETY.

The first meeting of this Society for the present Session was held on Wednesday evening, the 15th instant, at the Institution of Civil Engineers, Great George-street, Westminster; Dr. C. Theodore Williams (President) in the chair. Mr. F. J. Brodie read a Paper on

"The Great Drought of 1893, and its attendant Meteorological Phenomena."

After this, Mr. W. Marriott gave an account of the

"Thunder Storms and Hail Storms"

which occurred over England and the South of Scotland on July 8, 1893. Thunderstorms were very numerous on that day, and in many instances were accompanied by terrific hailstorms and squalls of wind. It was during one of these squalls that a pleasure boat was capsized off Skegness, twenty-nine persons being drowned. About noon a thunderstorm, accompanied by heavy hail and a violent squall of wind, passed over Dumfries and along the valley of the Nith; many of the hailstones measured from 1in. to $1\frac{1}{2}$in. in length. At the same hour a similar storm occurred at Peterborough. From about 2 until 10 p.m. there was a succession of thunderstorms over the north-east of England and south-east of Scotland, and at many places it was reported that the thunderstorms were continuous for nine hours. Two storms were remarkable for the immense hailstones which fell during their prevalence over Harrogate and Richmond in Yorkshire. The hailstones were 4in. and 5in. in circumference, and some were as much as 3in. in diameter. Great damage was done by these storms, all windows and glass, facing the direction from which the storm came, being broken. It is computed that within a radius of five miles of Harrogate not less than 100,000 panes of glass were broken, the extent of the damage being estimated at about £3,000. The thunderstorms in the northern part of the country travelled generally in a north-north-westerly direction at the rate of about 20 miles an hour. They appear to have taken the path of least resistance, and consequently passed over low ground and along river valleys and the sea coast. Several storms seem to have followed each other along the same track.

THE STORAGE BATTERY OUTLOOK IN AMERICA.*

The history of the storage battery in America presents phases of such anomalous character that it can be compared to that of no other electrical apparatus of like importance which has yet made its appearance. The readiness with which Americans are known to take up and bring into practical shape and use every invention and apparatus giving promise of commercial success seems, in this instance, to have been entirely wanting, with the result that to-day America makes, perhaps, the poorest showing in the application of storage batteries of any country of similar size and importance. To analyse the causes which have led to this, in many ways to be deplored result, would lead us too far; but we think they can be summarised in the statement that the proverbial American impatience for results, and inadequate attention to details in the early stages of the introduction of the storage battery, will account for many of the failures recorded. The excellent results which have, within the last few years, been attained in Europe with it have, we are glad to say, again forced the storage battery on the attention of our own electrical engineers, and we have of late discerned a reviving, and we hope an increasing, faith in the capabilities of the accumulator when properly applied. In central station practice the economy to be derived from operating engines at full load for a definite period, which the storage battery makes possible, appears to be now no longer a matter of doubt, judging by the results obtained abroad; and the recent trial of a like method of station operation in New York City corroborates this European experience.

But what is shown to be so eminently conducive to economy in lighting work, ought to be not less so when applied to electric railway operation. Much of the discussion which has been held on

* From the *Electrical Engineer* of New York.

Digitized by Google

the management of street railways has related to the most economical method of power equipment, and hence it is fair to assume that this item of railway expense is constantly before the eyes of street railway managers. With the usual load factor of railway power plants, and the enormous power fluctuations to which they are subjected, there would appear to be here a field for the storage battery, more extended even than in electric light stations.

But we must not lose sight of the direct application of the storage battery in railway work—the storage battery car. While the trolly system is unquestionably strongly intrenched, and at the time of its introduction confessedly presented the only available and practicable method for this country, no one will deny that it has its shortcomings; we may go so far as to say that street railway managers themselves would welcome a system which, in the first place, would dispense with the overhead system of conductors and all the troubles to which they are subject; and, in the second place, would make each car a self-propelling unit, independent of any other factor in the operation of the road.

The sporadic attempts which have been made to demonstrate the feasibility of storage-battery traction have not, we are sorry to say, proved convincing to the large majority of street railway managers, who are, perhaps, among the most conservative of business men to be found anywhere, and rightly so. Quite recently, however, the subject has again been taken up with energy, and in a manner which bids fair to demonstrate that the storage battery, applied directly to the car, can, under proper local conditions, hold its own against any other method of traction. We base this view upon the very systematic trial which is now being carried out by the Waddell-Entz Company on the Second Avenue surface road in New York, and which has extended over a sufficient lapse of time to enable a fair estimate to be formed of what the system is capable of accomplishing. The result obtained on the Second Avenue line has shown that in practicability and reliability storage-battery traction can be depended upon to fill the needs of the most exacting conditions; but, it will be asked, What does it cost? On this point we are enabled, through the courtesy of the Waddell-Entz Company, to give the cost of operation of their storage-battery cars on the Second Avenue road, as made up directly from the books of the Company. The figures of the actual cost, under the present conditions, with six cars in operation, show that the expense for power, including everything which properly belongs under that head, amounts to 9.32 cents per car-mile. This figure, of course, exceeds that which may be attained with the trolly system, but the cost for the same items of expense when figured on the basis of 18 cars would compare far more favourably with that of the trolly. If, in addition, we take into consideration the cost of overhead construction and its maintenance, the high efficiency at which the engines can be operated, and the other advantages accruing from having the entire operating force constantly under the eye of the superintendent, this disparity is still further lessened. It may take some time yet to heal fully the wounds of the past, but with a better understanding of the nature and capabilities of the storage battery America may yet turn its early storage battery experience to good advantage.

LEGAL INTELLIGENCE.

Thompson v. Cowles Syndicate Company.

In this action, the hearing of which by Baron Pollock occupied several days, the plaintiff was Mr. N. G. Thompson, engineer and agent, Victoria-street, Westminster, S.W., and the defendants are the Company which has been carrying on the process of producing aluminium and aluminium alloys by electrolysis by means of the Cowles electric smelting furnace. The plaintiff claimed £290 for carbon rods supplied; the defendants paid £90 into Court for a proportion of the carbons which were found suited to their purpose, but repudiated liability for the remainder, which they alleged were not suitable, and further brought a counter-claim for damage sustained by reason of this alleged unsuitability.

The plaintiff's case was that the carbons were supplied according to sample, were of good quality, and would have been found suitable for the purpose for which they were required if properly managed.

Mr. THOMPSON gave evidence as to the order for the carbons, which were obtained from the French firm for which he was agent in this country.

M. BERNE (the manufacturer) stated that the carbons were identical with carbons he had supplied to the Swiss Aluminium Production Company at Neuhausen for a similar process to that carried out by the defendants, and which the Swiss Company had found entirely suitable.

Mr. JAMES SWINBURNE said the carbons produced were capable of conveying the current used in the process without wasting, and he attributed the wasting alleged to have taken place to the over-heating of the bath into which the carbons were plunged. There was a slight difference in the hardness of the two sorts said to have been supplied, but not such as to have any material effect.

For the defendants, Mr. ESCHEWARI (manager of the Company) spoke as to the negotiations which took place between the Company and the plaintiff prior to the supply of the carbons. They had previously been using American carbons, which proved satisfactory; but when their stock of these was exhausted they gave plaintiff an order for 10,000 kilos of French carbons. With the American carbons they had been in the habit of producing about 200lb. of aluminium with a current of 3,000 amperes. In June, 1892, they received the first instalment of carbons from the plaintiff. When used the carbons appeared to get hot at the top, and they wasted away. Upon analysis they found 20 per cent. of carbon in the bath, which was rendered unworkable. Some carbons subsequently supplied turned out all right, although worked under identical conditions.

Mr. NICHOLSON said he was an electrical engineer. The wasting of the carbons at the sides, he considered, pointed to over-heating or to bad manufacture. If the carbons were up to the ordinary commercial standard they would not, in his opinion, have showed any signs of wasting with the current said to have been used.

Mr. MOULTON, Q C., for the plaintiff, contended that the whole of the mischief was caused by the over-heating of the bath upon the occasion when the first carbons were tried.

Mr. BOUSFIELD, Q.C., in reply, asserted that the conditions were in no way different from those which prevailed when the carbons were used which worked satisfactorily.

Baron POLLOCK, in giving judgment on Tuesday, held that an inferior quality of carbons had clearly been supplied, and the plaintiff could not, therefore, recover for them; but that there was no warranty and no special damage proved. There would, therefore, be judgment for the defendants, with costs, except as to the counter-claim, in regard to which there would be judgment for the plaintiff.

Mr. TINDAL ATKINSON, for the plaintiff, asked for a stay of execution for a week, pending appeal, and this was granted upon the condition that £100 was paid into Court as security for costs.

Elieson Accumulator (British Patent) Syndicate (Limited) v. The Earl of Galloway

This case, which was part heard before the Long Vacation, was resumed in the Queen's Bench Division on Tuesday before Mr. Justice Kennedy, sitting without a jury.

The plaintiffs in the case are the Elieson Accumulator (British Patent) Syndicate, a Company incorporated October 15, 1892, for the purpose of working an electric patent and plant at Croydon, which the inventor, Mr. C. P. Elieson, had disposed of for £6,000 fully-paid up shares in a Company to be subsequently formed. The plaintiffs alleged that the defendant (the Earl of Galloway) applied for 2,000 shares, and paid a deposit. Application having been made for payment of the balance, the defendant refused to carry out the contract. The defendant denied the agreement, and also denied that shares had been allotted to him. The Earl of Galloway also pleaded that the Company registered on October 13, 1892, was not the Company agreed upon; that subscriptions to the amount agreed upon from the outside public had not been forthcoming; and he was not, therefore, liable, as he had not applied, and had given no authority to the promoter to apply, for shares. Mr. C. Salter appeared for the plaintiffs; Mr. Frank Lockwood, Q.C., and Mr. Pollard represented the defendant.

His LORDSHIP, upon taking his seat, said as he recollected the case the question was whether there was a valid allotment of shares for which Lord Galloway was bound, and certain letters and a verbal promise were relied on to attach responsibility for the shares. The defendant denied agreement to take, and said if there was it was subject to an agreement with Lord Sackville Cecil.

Mr. LOCKWOOD said that was the substance of the case so far as it had progressed; but it was further contended by the defendant that there should be directors approved of by Lord Galloway. There were two prospectuses, one in relation to a storage company, and another in respect to an accumulator company, there being £50 paid in respect to each company, but treated as a deposit upon an additional 1,000 shares in the plaintiff company. The defendant denied that there was any allotment, or that there had been any application by the public to the amount agreed upon; and he further denied that he had paid the £100 as a deposit upon shares in the Company.

Mr. WATSON SMITH, the promoter of the Company, and other witnesses, having given evidence,

Mr. LOCKWOOD, Q.C., addressed the Court for the defendant, and

Mr. ELIESON, the inventor of the accumulator patent, was examined on behalf of defendant, and denied that there had ever been any confirmation of sale given by Mr. Alfred Pallas, his partner, such as that spoken of by Mr. Watson Smith. He denied that he had ever entered into a contract with the plantiff company, and said that his patent had been sold to another and a different company, which is now in existence.

The EARL of GALLOWAY was examined, and generally bore out counsel's statements in his behalf. He denied having given Mr. Watson Smith authority to apply for shares in any other companies than those mentioned in the prospectus. He admitted having signed an application for shares under a certain prospectus of a company which was to be formed, but which never was formed.

After addresses upon both sides, his Lordship reserved judgment.

The Medical Battery Company (Limited).

Mr. C. B. Harness, aged 47, living at Heathside, Potter's Bar, and well known in connection with the Medical Battery Company (Limited), and with what is now known as the Electropathic Belt Fraud, was charged on remand at the Marlborough-street Police-court on Wednesday with unlawfully conspiring, confederating, and agreeing with Dr. J. Montgomery McCully, and other persons, by false pretences and fraudulent advertisements in newspapers and otherwise, to defraud; further, with conspiring with other persons to obtain by a false and fraudulent pretence the sum of

Digitized by Google

£52. 10s., and other sums of money from Colonel Jeremiah Braysyer, with intent to defraud; and further with obtaining the sum of £2. 2s. from Frederick Theobald Burbage, and the sum of £2. 2s. from William Hibberdine Manners, in each case with intent to defraud. James Montgomery McCully, 47, a physician, living in Blandford Mansions, East-street, Marylebone, and Charles Beavington Hollier, 37, described as a salesman, of the Headley Arms Hotel, Warley, Sussex, were charged, on remand, with conspiring with Harness in committing the alleged offences.

Mr. Thomas Terrell, barrister, prosecuted: Mr. Horace Avory appeared for Harness, Mr. A. R. Cluer for McCully, and Mr. C. F. Gill for Hollier.

Great interest was taken in the case by the general public, who crowded the court; and Mr. Terrell, in opening the proceeding, detailed a number of cases in support of the action taken by the prosecutors; and evidence was given by a former employé of the Medical Battery Company in support of the prosecution. In the course of his opening statement Mr. Terrell informed the Bench that he was prepared to prove conclusively before the case was concluded, by calling some of the most eminent electricians of the day, that the so-called electrical belts had no possible electrical effect whatever. He described Harness as a "vulgar, ignorant man, with no knowledge of any kind except that of selling goods." The business of the Medical Battery Company was kept together chiefly by advertising, upon which enormous sums were spent annually, reaching in one year as much as £50 000! McCully, who represented that he was a qualified medical man, was some years ago struck off the register. Hollier was a salesman who represented himself on many occasions to be Harness. On one occasion, when Harness was asked a question as to the elements of electricity, he replied that he "did not trouble himself about the groundwork of science, but went straight up to the highest flights."

The accused were ultimately again remanded for a week on bail.

The adjourned petition to compulsorily wind up the Medical Battery Company was heard by Mr. Justice Vaughan Williams on Wednesday. Since the presentation of the petition the Company has passed a resolution to wind up voluntarily.—Mr. Bramwell Davis also asked for a compulsory order on behalf of Sir William Long.—Mr. Boxall, representing shareholders to the amount of £43,8 0, favoured the suggestion as to voluntary liquidation, so that "a valuable business might continue."

Mr. Justice WILLIAMS: I am not aware that there is any such valuable business.

Ultimately, his Lordship ordered the continuance of the order for voluntary winding up under supervision for a week.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 4, 1893.

The Westinghouse Company.—This Company has been awarded a contract for three two-phase alternating-current dynamos of 5,000 H.P. each, of a design originating with engineers of the Niagara Falls Power Company. The E.M.F. will be from 2,000 to 2,400 volts, which will be increased by step-up transformers for long distance transmission and lowered by step-down transformers for distribution. A remarkable point in regard to the system thus definitely adopted is that the frequency will be only 25 periods per second.

Electricity for Canal Boats.—At the last session of the New York Legislature a sum of money was appropriated to experiment with electricity for towage purposes on the Erie Canal. This has furnished an attractive theme for the newspapers, which have devoted considerable space to this new application of electricity. A trial will soon be made over a short distance with a trolly system, but it is not thought that any of the experiments will have practical results.

Trolley Accidents.—The newspapers continue to teem with accounts of trolley accidents, which with scarcely a single exception were caused by persons being struck or run over by electric cars. The State Railroad Commissioners of New York are now considering the subject of regulations for electric street railways, and it is probable that they will place a limit on the speed, require cars to be equipped with suitable fenders and with a reliable system of brakes. Some of the more serious of the recent accidents have been caused by the brakes refusing to work at the critical moment.

Municipal Lighting Plants.—The subject of municipal electric lighting plants is becoming more prominent; several large cities have declared in favour of municipal plants, and quite a large proportion of the new town plants in New England and in the West were built by public funds authorised by large majorities at elections held for the purpose.

CORRESPONDENCE.

THE POLLAK ALTERNATE-CURRENT COMMUTATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of November 3rd you make some remarks with respect to my device for commutating alternating currents described in the same number of your valuable paper. The process is, in your opinion, very wasteful and troublesome. Allow me to say that the efficiency of the transformers has proved, after exact measurements, made here as well as in Chicago, to be but very little lowered in applying them to my apparatus, the extra loss being from 1 to 5 per cent. The trouble, too, which is caused by the manipulation of the "rectifier" is very small, requiring no more attention or skill than a dynamo machine; the displacement of the brushes necessary to do away with sparks is, in charging storage batteries, necessary only during the initial and the final period, where the rise of the counter E.M.F. is rapid; for the purpose of driving direct-current motors automatic regulation is provided. The device is not only applicable to small installations; on the contrary, it is the more efficient and cheap, the greater the current, because it can wholly replace the motor-dynamo otherwise used. Nevertheless, I venture to say that where there is an alternating current supply, and a demand for 2 H.P. continuous current, my device would be far simpler and cheaper in first cost and maintenance than a gas motor and dynamo, and give an efficiency by itself of 95 to 98 per cent., which cannot be obtained by a 2-H.P. isolated plant. As to the difficulties of measurement alluded to, they are in practice by no means as great as it would appear, experience showing that nearly the same amount of power, the same time, and exactly the same instruments as in direct-current work are required for definite results. I am quite ready to prove this assertion by showing my device to anyone taking interest in the question.

Hoping you will give room to these lines in your next issue.—Yours, &c.,

C. POLLAK.

Frankfort, November 13, 1893.

[It was to the use of a transformer with a highly-saturated core, and not to the general working of the commutating device, that our remarks about wastefulness were directed. We observed indeed that the system appeared to give fairly efficient results. For electric lighting it is generally sufficient to measure the current, or the $\sqrt{\text{mean}^2}$ of the current. But in charging accumulators it is often necessary to know the quantity as well as the dynamical value of the current. As there are periods during which no current whatever flows, in this system, we do not see how it is possible to measure the ampere-hours put into a battery. In the laboratory to which we alluded, such measurements are essential.—ED. *E.*]

THE GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A misleading circular signed "Scrutator" has been addressed to some of the shareholders of the Globe Telegraph and Trust Company (Limited), insinuating that the present value of its assets shows a deficiency in its capital account, and I am directed to ask you to be good enough to publish the following:—

The Directors yesterday caused a valuation to be made of the securities held, and this shows a present surplus market value over the paid-up capital of the Company of close on £300,000.

I beg to enclose you a copy of the balance-sheet of July 18, 1893, and you will find attached thereto full details of the Company's investments, which have not since been varied. The values of all but two or three comparatively small investments are quoted daily, and it will be easy for any shareholder to satisfy himself of the accuracy of the above-mentioned valuations.

Digitized by Google

At the same time, I am instructed to say that the Directors do not consider the market prices of the securities they hold as being the only criterion of their values.—Yours, &c.,

SIDNEY COLLETT, Secretary.

Winchester House, Old Broad-street, London, E.C.,
November 16, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, which has a special interest at the present time, is now ready, and will be forwarded on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus can be obtained on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready, and will be sent direct on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus will be forwarded free on application.

TENDERS INVITED.—Tenders are invited for the extension to Laxey of the existing electric tramway from Douglas to Groudle Glen. Plans may be seen, and specifications, &c., obtained at the office of Mr. F. Saunderson, 7, Athol-street, Douglas, Isle of Man, to whom tenders must be sent by the 25th inst.

TENDER ACCEPTED.—The Staffordshire County Council have accepted the tender of Messrs. Rooper and Tozer for the providing and fixing of wiring for the electric light for the Council's new buildings for the sum of £460. The specifications for this work were prepared by Messrs. Kincaid, Waller and Manville.

APPOINTMENT VACANT.—The Crown Agents for the Colonies, Downing-street, London, S.W., will receive up to November 30th, applications for the post of telegraph mechanician for the Telegraph Department of the Gold Coast, West Coast of Africa, at a salary of £200 per annum, rising by annual increments of £25 to £250 per annum. Other particulars will be found in our advertisement columns.

——— The City and Guilds of London Central Institution (Physical Department) require two assistants. Applications must be sent in to Prof. Ayrton, at the Central Institution, Exhibition-road, London, S.W. Some further particulars are given in our advertisement columns.

LIQUIDATIONS.—At meetings held on October 14th and November 4th, the shareholders of the Halifax Mutual Electric Light and Power Company (Limited) resolved to voluntarily wind up the Company, and appointed Mr. W. D. Taylor, Town Hall-buildings, Halifax, as liquidator. Claims against the Company are to be sent in by December 16th.

——— The members of the Engineering Exchange (Limited) have resolved that the concern be voluntarily wound up, and Mr. A. T. Salisbury-Jones has been appointed liquidator.

——— A meeting of the Eclipse Electric Lighting Syndicate (Limited) is to be held at 8, Finsbury-circus, E.C., on December 18th, for the purpose of receiving the report of the winding up.

MESSRS. JULIUS SAX AND CO. (LIMITED).—Prince Louis of Battenburg on Tuesday last visited the works of Messrs. Julius Sax and Co., at Ridgmount-street, and inspected the new flash lamp, which is intended for signalling purposes in the Navy, and has been adopted by Sir William Armstrong, Mitchell and Co., of Newcastle.

THE ROBERTSON LAMP.—We have received from the General Electric Company a table showing the cost of electric lighting when using "Robertson" lamps of 16-c.p. at various efficiencies. The table is calculated on the basis of a one-and-sixpenny lamp, and that lamps are considered renewable when they have lost 25 per cent. of their original candle-power. In the table we find, for example, that at 6d. per unit, and at 4 watts per candle, the total cost per lamp hour is 0·397d., of which 0·013 is the cost of renewals. At 3·5 watts per candle it is 0·354d., the renewals being 0·018d.; at 2·5 watts per candle the renewals come to 0·05d. and the total cost 0·29d., while at 2 watts the renewals are more than twice the last figure, viz., 0·11d., and the total cost has risen slightly to 0·302d. It is guaranteed that the Robertson lamps will not take more current on an average, during their "efficient life," than the values given in this table.

CORLETT ELECTRICAL ENGINEERING COMPANY (LIMITED).—This company have opened a branch office at Newcastle-on-Tyne, under the management of Mr. C. W. Fairweather, late works manager to Messrs. Ernest Scott and Mountain.

PHOSPHOR BRONZE.—The Phosphor Bronze Company inform us that they have appointed Messrs. Dempster, Moore & Co., of 49, Robertson-street, Glasgow, sole agents in Scotland for the Phosphor Bronze Company's manufactures.

STORAGE BATTERIES AT BIRMINGHAM.—The Electrical Power Storage Company (Limited) inform us "that the Birmingham Central Tramways Company have (as will be seen from attached extract from their letter), after trying plates of other manufacturers for more than a twelvemonth, decided to renew the whole of the battery with E.P.S. plates. Two batteries of the original plates manufactured by the Electric Construction Corporation (the then owners of the E.P.S. patents), supplied more than two years ago, have been regularly working and giving excellent results. Owing to the manner in which the 'Results' on this particular line have been persistently advertised, we trust you will give this statement due prominence." The following is the extract referred to above:—

"To the Electrical Power Storage Company (Limited),
"4, Great Winchester-street, E.C.
"November 10, 1893.

"Birmingham Central Tramways.

"Dear Sirs: With reference to your favour of the 1st instant, we beg herewith to order from you, on behalf of the Birmingham Central Tramways Company, 960 positive sections, each of nine plates; and 960 negative sections, each of ten plates, in exchange for plates of other makers, as set forth in your letter of November 1st.

"Yours faithfully,
"(Signed) KINCAID, WALLER AND MANVILLE."

In reference to the above we are asked by the Epstein Electric Accumulator Company (Limited) to insert the following:—

"21A, Blyth-road, West Kensington, London, W.,
"November 15, 1893.

"From a letter of the Electrical Power Storage Company it would appear that out of the number of E.C.C. batteries supplied to the Birmingham Central Tramways Company about two years ago two have been regularly working till now, and giving excellent results. This is not according to facts. On the other hand, the results which have from time to time been published by the Epstein Electric Accumulator Company (Limited) are based on indisputable facts, and their correctness can be easily ascertained. The statement as to the lifetime, reliability, and absence of repairs and renewals were made publicly, and confirmed by those best able to judge, being in possession of official figures.

"The experience and responsibility of the gentlemen who are entrusted with the management of the affairs of the Birmingham Central Tramways Company should offer a sufficient guarantee that the order given to the Electrical Power Storage Company is coupled with a maintenance clause, and it would be doubting their business capacity if one presumed that the terms of the contract are not more to the interest of the shareholders than the offer made by the undersigned Company to work the line and defray all expenses, with the exception of permanent way and general charges, for 70 per cent. of the gross receipts.

"But electrical and tramway engineers would no doubt feel greatly obliged if the information regarding the lifetime, repairs and renewals of the accumulators, and the financial results to the supplying and maintaining company were officially vouchsafed from time to time."

HENLEY'S CABLES.—We have received a new price list of electric light cables and wires made by W. T. Henley's Telegraph Works Company. The insulation resistance given in each class is the minimum resistance guaranteed for the largest cable in that class, and as the cables decrease in size the insulation resistance increases. In the smaller cables the ratio of the thickness of the insulation to the diameter of the conductor must be increased for mechanical purposes. The tables are very clearly arranged, the particulars of the conductors being repeated on each opening. Mr. Preece's Paper on this subject has borne good fruit in the production of such price lists as this.

ELECTRICITY IN MINES.—The Moodie Gold Mining and Exploration Company of South Africa have concluded contracts with Messrs. W. T. Goolden and Co., for the supply and erection of plant for the electrical transmission of 250 H.P., generated by water-power from the Queen's River, to the various mines situated near Barberton, a distance of about ten miles. This is the most important power transmission scheme yet undertaken in South Africa, and if successfully carried out will have an important bearing on the future of many of the South African gold fields.

FALKIRK IRON COMPANY.—Mr. T. W. Alsop, manager of the Falkirk Iron Company, requests us to state that this company has no connection whatever with the London and Falkirk Foundries Company (Limited), the prospectus of which has been circulated this week. As the Falkirk Iron Company is well known to many, more especially in Scotland, by the name of the Falkirk Foundry, Mr. Alsop is anxious that it should be generally known that there is no connection whatever between the two concerns.

ELECTRO-HARMONIC SOCIETY.—A "Ladies' Night" will be held at the St. James's Hall Restaurant, Regent-street, W., on Friday, the 24th inst., at eight o'clock. An interesting programme will be provided.

Digitized by Google

BARROW.—The Town Council last week decided to apply for a Provisional Order.

BATTERSEA.—The new Town Hall on Lavender-hill was opened by Lord Rosebery on Wednesday. The *Daily News* says that there are only two points of deficiency likely to strike the stranger who strolls through it—one being the want of the electric light instead of gas, and the other the absence of an organ, or a place for an organ, in the large public hall. Our contemporary says: "We understand that gas was adopted because there is, as yet, no installation or electric supply in the neighbourhood, and it would have added some £3,000 or so to the cost of the undertaking to have set up an independent supply. It seems almost a pity, though, not to have made at any rate necessary provision for electricity when by-and-by it has become available."

BUXTON.—The Local Board have decided to apply for a Provisional Order.

CAMBERWELL.—At the meeting of the Vestry held last week the Electricity Committee produced a list of streets through which they recommended the Vestry to lay electric mains. Some opposition was raised to the scheme, but after several divisions the Committee's recommendation was carried by a small majority.

CAMBRIDGE.—At the last meeting of the Town Council the Electric Lighting Committee reported that they have received a letter from the manager of the Cambridge Electric Supply Company (Limited) pointing out that at present the Company had to maintain a constant supply of energy, which resulted in considerable pecuniary loss to the Company, without any corresponding benefit to the public. They therefore desired to come to an agreement with the Corporation that there should be exceptions to the delivery of a constant supply. The Committee recommended that from the present time until the 31st day of December, 1894, the Company be permitted to make the following exceptions to a constant supply, viz.:—On weekdays, from October 1st to June 25th inclusive, from 2 a.m. to 6 a.m.; from June 26th to September 30th inclusive, from 2 a.m. to 5 p.m. On Sundays, from April 1st to September 30th inclusive, from 1 a.m. to 6 p.m.; from October 1st to March 31st inclusive, from 1 a.m to 4 p.m. But in no case on Sundays shall the supply be shut off after sunset. Some opposition was raised to the proposal on the ground that the application was an attempt on the part of the Company to evade the conditions under which they had undertaken to supply the electric light, and the consideration of the report was postponed until the next meeting of the Council.

CARLISLE.—On Wednesday last week the library of the Institute of Literature, Science, and Art, established by the Corporation at Tullie House, was formally opened by the Mayor. The building is lighted by electricity from plans provided by Mr. Howard-Smith, the city surveyor, under whose superintendence the installation was fitted up. The current is generated by two Latimer Clark dynamos, driven by Tangye gas engines. Over 400 incandescent lamps from 8 to 50 c.p., are distributed over the building. The contractors for the electrical work were Messrs. Latimer Clark, Muirhead and Co., and the work was carried out by their representative, Mr. W. E. Weise.

CHAGFORD.—At a Vestry meeting held last week it was decided to continue the lighting of the town by electricity.

CHERTSEY.—At the last meeting of the Rural Sanitary Authority the clerk was directed to again inquire of the Weybridge Electrical Supply Company when they intended to carry out their promise to place their conductors underground, and to ask them for their terms for the future lighting of the parish, the present contract having nearly expired.

CHICHESTER.—The last meeting of the Town Council had under consideration the electric lighting scheme suggested by Mr. Prior, an abstract of which has appeared in *The Electrician*, and after some discussion the Lighting Committee were instructed to take the matter into further consideration and report thereon.

CRIEFF.—Some time ago a proposal was brought before the Town Council for the introduction of the electric light into the town. Since then Sir Patrick Keith Murray, Bart., of Ochtertyre, has offered the use of the Falls of Barvick, two miles from the town, to be utilised for the motive power for generating the light; and at a meeting of the Council on Monday, Provost Adie urged upon the Board to take advantage of Sir Patrick's offer, and stated that he would shortly lay before the Board a scheme for this purpose.

GUILDFORD.—In June last the Holloway Electricity Supply Company (Limited) gave notice to the Corporation of their intention to apply to the Board of Trade for a Provisional Order, and last week Mr. Sidney Sharp attended a public meeting as representative of the company. He suggested that the company should be formed locally, and that a station should be erected sufficient for 4,000 8-c.p. lamps, the approximate cost of which would be £10,000. The proposal was well entertained by those present, but in order to get a more representative gathering the meeting was adjourned until Monday, when a Committee was appointed to consider the question.

KILLARNEY.—At the last meeting of the Town Commissioners, the contract for the lighting of the town by the gas company came up for signature. The Town Clerk read a telegram he had received notifying him that the matter was to be brought before the Queen's Bench, Dublin, and notice was given of a resolution to be moved at the next meeting of the Board, that the gas tender be rescinded, and the matter of the public lighting be reconsidered. After some discussion it was moved and seconded that the gas tender should be signed by the Chairman, and sealed, but on a division this was lost.

LANDORE.—It is stated that a proposal is on foot to establish in the neighbourhood of Landore large new works for the electrical deposition of copper and other metals.

LEYTON.—The Electric Light Committee reported at the last meeting of the Local Board that, in their opinion, it is not necessary to consider any scheme in detail for lighting the district, or any part of it, by electricity until further progress has been made with the Provisional Order about to be applied for, or such order has been obtained. The Board adopted this report.

NICE.—The electric light installation at Nice is expected to be completed by Christmas.

OYSTERMOUTH.—The Local Board of Health have requested their engineer to prepare and submit to them a report upon the installation of the district with the electric light.

POOLE.—Powers were recently obtained for the construction of an electric tramway between Poole and Bournemouth, and for the supply of the electric light to Poole and Parkstone. An influential meeting of the inhabitants of Poole, Parkstone, and Bournemouth was held last week at Poole to consider whether it would not be more economical to amalgamate these two schemes under one management. After a long discussion the meeting unanimously approved of the suggested fusion.

RAMSBOTHAM.—The Local Board last week decided to make application to the Local Government Board for a Provisional Order.

SMOKELESS COAL.—The City of London Electric Lighting Company (Limited) were summoned last week at Southwark for not using smokeless coal. The defence was that, owing to the coal dispute, the Company had been unable to obtain a supply of smokeless coal for which they had contracted, although they had offered 10s. per ton over the contract prices. It was impossible for them to stop their works without breaking their contract for the electric lighting of the City, and they were compelled to use whatever coal they could obtain. It was hoped, however, that the difficulty in this matter was at an end. The Magistrate adjourned the case for a month, in order to see if the nuisance were abated.

STEALING ELECTRIC WIRE.—At the Glasgow Sheriff Criminal Court on Friday, Walter Burns was sent to prison for three months for stealing 1,260 yards of copper telephone wire on the public road between Govan and Renfrew; and Walter Corbett was sentenced at the Old Bailey on Tuesday to six months' hard labour for stealing 56lb. of copper telegraph wire, which he had cut on one of the Post Office lines.

SUTTON.—Mr. E. C. De Segundo has forwarded a report to the Local Board suggesting that they should put in a small electric light installation for supplying the shops and public buildings in the High-street at a cost for plant of about £4,000. The actual expenses of such an installation he estimates at £500 and the receipts at £830, showing a profit, after paying the interest on the borrowed money, of £210.

SWANSEA.—The Swansea Electric Lighting Order is about to expire, and Messrs. Crompton and Co. (Limited) will apply for a Provisional Order to light the town by electricity.

VENICE.—The Municipality have given permission for electric launches to be used on the canals, and a trial trip was recently made with a launch constructed to carry twenty-eight persons.

WEST HARTLEPOOL.—The Town Council decided at their last meeting to apply to the Board of Trade for a Provisional Order.

WOLVERHAMPTON.—The Lighting Committee of the Corporation in their annual report, laid before the last meeting of the Council, dealt with the question of electric lighting for the borough. The Committee stated that plans and specifications were in course of preparation, and that Mr. F. H. Lewis, the electrical engineer, was in negotiations with the Electrical Construction Company with a view of obtaining a modified tender from them for the plant and machinery necessary to supply electricity for 5,000 incandescent lamps and 40 arc lamps for street lighting, also with Mr. John Thomson for the boilers, and the Callendar Company for the laying of cables, &c. The Council adopted the Committee's report.—It is reported that some extensive engineering and electrical works are about to be erected on the Wednesfield-road. The site consists of between three and four acres of level land, and is in close proximity to both the Midland and Great Western Railways. Details as to the scheme are not yet published; but it is understood that the works will be of an extensive character.

COMPANIES' MEETINGS.

West India and Panama Telegraph Company (Limited).

The thirty-third ordinary general meeting of the members of this Company was held at Winchester House, on Wednesday, Mr. C. W. Earle presiding.

The ACCOUNTANT (Mr. J. L. Quick) read the notice calling the meeting, in the absence of the Secretary (Mr. R. T. Brown), and he afterwards read the minutes of the last ordinary and extraordinary general meetings. The report of the Directors was taken as read.

The CHAIRMAN then said: Gentlemen, by a strange recurrence of fatality, it happens that this is the third consecutive half-yearly report in which we have had to announce the death of one of the members of this Board which was elected by the committee of shareholders very nearly 20 years ago. I think that those gentlemen—I see some of them present—who took part in the discussions which resulted in the formation of that committee of investigation, will remember that its object was to place on this Board men of practical experience in telegraphic business. At that time I do not suppose there was any man in England, with the exception of my friend, Mr. Andrews, who had such a long experience of every detail of the management of a telegraph company as the late Mr. Weaver. He had filled various offices with the Electric and International Telegraph Company, which was the *principal* owner of the lines working in the United Kingdom before the telegraphs were acquired by the Post Office. I first knew Mr. Weaver when I was a member of that Board in the year 1865, and it was from him that I got what little smattering I possess of the details of telegraphic administration. When the State acquired the telegraphs, they appointed Mr. Weaver as the arbitrator for the Post Office in settling the price at which the railway companies' telegraph lines were to be taken over by the State; and I do not think there could have been a greater compliment paid to his knowledge of the subject and to his integrity than that appointment. Since then Mr. Weaver had had the management of the Anglo-American Telegraph Company, and he discharged the duties of that office up to the time of his death. This Company owes a great deal to Mr. Weaver. His experience and intimate knowledge of his business, coupled with that of Mr. Andrews, and supported by the rest of the Board, was chiefly instrumental, I think, in introducing order and system in place of the somewhat chaotic condition of things in which we found the telegraph service of the West Indies at the time we took over the affairs of the Company. I am sure that we owe Mr. Weaver in many ways a great deal of gratitude for what he did, and I am equally certain that my colleagues, who have known him and worked with him so long, feel very great sorrow that he is no longer with us. The times are somewhat changed since this Board was elected, and the necessity for the telegraph experience and power of organising a telegraph company's system is not so important now as it was then. In fact, the system inaugurated by the gentlemen I have mentioned continues to work well, and our staff are perfectly well acquainted with the ordinary rules of working a telegraph company. We have, therefore, thought it well to strengthen our body in another respect, and have requested Mr. Gerald Balfour, M.P., whose ability and position will be of advantage to us, to join our Board, and he has accepted our invitation. Looking now at the accounts and the report, I think we may congratulate ourselves on having had, for this Company, rather a satisfactory half-year. The normal proper traffic has increased somewhat from the great falling off that occurred through the reduced rates forced upon us in 1891; and owing to an accident to our competitors, the French Cable Company, by the breakdown of their cable between Hayti and Cuba, their traffic came over our line at Martinique, and gave us an increase of about £2,800 during the seven weeks they were interrupted. Another piece of good fortune for us was the diminished expenditure upon repairs of cables, under the head of Abstract C. That is, of course, a mere matter of good fortune. The very large difference between the expenditure in 1892—in which year, you may remember, we charged some £8,000 odd to the reserve fund—amounts to £12,358; and it is rather significant, as showing how risky, how variable the position of a company like this is, with so small a revenue, that the difference between the expenditure on cable repairs in 1892 and in 1893 is equal to about 25 per cent. of our gross receipts for six months. We have thought we could now do for a time, at any rate, with only one ship on the West Indies, and have therefore re-called the "Duchess of Marlborough." We have had this vessel repaired, and she has passed her survey, and is now lying in the West India Docks. I hope it will be long before we require her again; but if, through any interruption or misfortune of that sort, we should do so, she is ready to be commissioned and to resume the work she was formerly employed on. I now come to paragraph 6 of our report. It has long been a source of regret to me, with the very excellent staff we have, many members of which have been 20 years in our service, that we could do so little to improve their position, owing to the very unremunerative condition of our business. As you are all probably aware, the system of insurance has had a very great extension of late years. It is even proposed, I believe, by some statesmen that every one should be insured at the national expense. At any rate, with respect to telegraph companies, which more particularly come under our notice, it has been of late years a very general practice to assist the staff in obtaining the benefits of insurance. I think it will be good policy, as well as justice to the men who have served us so long and faithfully, to help them by some means in view of the time when they come to retire. I cannot say what the cost of the assistance we propose to give them will be—it will depend very much upon how far it is taken up by the staff; but I think I can promise you this, that there will be a good margin between the expense which this will entail and what we have saved by not filling up the two vacancies on the Board. We have, in fact, taken upon ourselves as Directors the additional labour caused by the death of two gentlemen, and we hope you will allow us to spend some part of the saving thus effected by benefiting the staff. If any shareholder wishes to ask me any question I shall be very glad to answer him, but meantime I will propose the following resolution:—

"*That the Directors' report and accounts to June 30, 1893, submitted to this meeting be, and are hereby, received and adopted; and that, as recommended by the Board, dividends of 6s. per share on the First Preference shares, 6s. per share on the Second Preference shares, and 1s. per share on the Ordinary shares—the latter free of income-tax—be, and the same are, hereby declared.*"

Mr. WILLIAM ANDREWS seconded the motion.

Mr. FRY said that he trusted he might be allowed, as a shareholder who had been interested in the Company for a number of years, and who had seen the good work which the Directors had done, thoroughly to endorse the remarks which the Chairman had made with regard to the loss sustained by the Company through the death of Mr. Weaver, who was believed in by all the shareholders in their Company, and in any other Company with which the deceased gentleman was connected. In their report the Board said that to fill the vacancy created by Mr. Weaver's death they had elected Mr. Balfour, "under the powers given to them by the Articles of Association." He desired to ask whether Mr. Balfour had been interested as a shareholder in the Company for any time, whether he represented any large interest in the Company, and whether he had any connection with any other telegraph company.

Mr. R. J. KING also expressed regret at the death of Mr. Weaver, whose value, he said, the Chairman had set forth most truly, and whose experience in the telegraph world must have been inferior to that of no one. He grieved to think that the Company had not suffered only a single loss, but that three deaths had taken place among them since the reconstituted Board was formed. The deceased gentlemen were distinguished members of the telegraph world, and had no doubt, as the Chairman had stated, been of essential service to the Company in extricating it from its difficulties and putting the shareholders into the comparatively comfortable position in which they now found themselves. With regard to the election of Mr. Balfour he also desired to know, like the shareholder who had preceded him, whether Mr. Balfour had any knowledge of telegraphy. Although the Chairman had said that the particular knowledge which was once necessary for the Company was now of less importance than it was when the reconstituted Board took office, he (the speaker) thought it desirable that the Directors should be gentlemen knowing something about the conduct of telegraph companies. He had not the pleasure of knowing anything about Mr. Balfour, but he trusted, for the sake of that gentleman himself, that he was no connection of the man whose name had become so thoroughly obnoxious to all respectable citizens. He congratulated the Company on the progress it was making, notwithstanding the difficulties against which the Directors had to contend. The French competition and other disappointments, and the loss of subsidies, were serious, but he thought they had reason to congratulate themselves on the fact that the skill of the Board had enabled them to devise means in some degree to counterbalance the losses thus sustained. He only hoped that they would continue to progress.

Mr. W. GRIFFITH thanked the Chairman for the lucid statement which he had made to them, as the figures alone would not have given the shareholders so clear an understanding of the position of the Company as the addresses they had listened to had done. The Chairman had taken the shareholders into the confidence of the Board, and he thought they might say that their Company was in a sound state, although, at the same time, they had a somewhat gloomy prospect before them. The fact that they had not yet recovered the losses which occurred from the diminution of the subsidies showed, he held, that they had been almost too liberal in regard to their tariffs. The West India islands were greatly indebted to the Company for what it had done, and yet, although its traffic fell off, and the dividends of the shareholders were likely to become less, they found their subsidies decrease. With reference to the proposal that they should consider the services of their old servants, he thought that the Directors would have the shareholders at large with them in what they suggested. Other telegraph companies had adopted a similar course, and he thought it was wise, in these days of competition, that they should retain in their service able and faithful men, and that the latter should have the prospect of a competence in their old age, and not be distracted in the performance of their duties by having to consider their wants hereafter. The details of the scheme required consideration, and if the Chairman could furnish them with some of the details beyond the general statement he had made, that the expense would be somewhat less than the income of two of the deceased Directors, the shareholders would be able to form some opinion of the matter. Beyond that they need not go on that occasion. He hoped the servants would be liberally treated, and that the Company would retain their services. He would like to know whether it was proposed that the insurance of the staff should be effected with one office only, or with various offices. He believed the latter system would be best, as in that way the Company might increase its *clientèle*.

The CHAIRMAN: I am rather sorry that the question of the appointment of Mr. Balfour has been raised, because it is a matter we discussed a great deal at this Board, and we saw very good reasons for asking him to become a Director. As I said, we do not now want the organising talent which we required in 1873 and 1874. The system has got into perfect order, it works uniformly, our servants are all experienced, and we have still on the Board Mr. Andrews, who is quite as capable in these matters as was

Digitized by Google

the late Mr. Weaver. There are, however, other points in a man of Mr. Balfour's position which are of importance to us, and I trust that you will not exact from me more upon this matter than I am now stating. You may depend upon it that the request which was made to Mr. Balfour to join our Board was done in the best interests solely of the Company whose affairs we have to administer. There are questions with the Government, in regard to which the mere technical knowledge of telegraphy would not be so valuable as the services which a man in Mr. Balfour's position may render to us. Of course, he is no connection with Jabez Balfour. He is a brother of the leader of the Opposition in the House of Commons. With reference to the question of insurance, we have not yet thrashed out the details. We shall go to a good many offices, and the one that we get the best terms from, being a reliable office, we shall probably adopt.

Mr. ANDREWS: You always get better terms in that way.

The CHAIRMAN: Yes, the terms are always better if the business is given to one office.

Mr. FRY said he assumed that Mr. Balfour represented no other interest on the Board, and that he was quite a fresh shareholder.

The CHAIRMAN: He has been an old shareholder, but he was not a shareholder at the time he was asked to join the Board. I may remind you that the gentlemen who were appointed by the committee of investigation were non-shareholders at the time.

Mr. FRY said that among the shareholders there were several who were largely interested in the Company who were thoroughly capable men of business, and who might be appointed Directors when the necessity arose.

The CHAIRMAN: I think you must allow us to deal with matters of this sort as we think most advisable in the interests of the Company. He then put the resolution, which was carried unanimously.

On the motion of Mr. KING, seconded by Mr. CHURCH, a cordial vote of thanks was passed to the Chairman and Directors for their able management of the Company's affairs.

The CHAIRMAN: We are very much obliged to you for your vote of thanks and your testimony that you approve what we have done. I am quite sure that we shall continue to do all we can to promote the interests of the Company as long as you give us your confidence.

The proceedings then terminated.

Western and Brazilian Telegraph Company (Limited).

The twenty-sixth ordinary general meeting of this Company, was held yesterday at Winchester House, Old Broad-street, E.C., under the presidency of Mr. W. S. Andrews.

The SECRETARY (Mr. R. M. Cunningham) read the notice calling the meeting and the minutes of the last general meeting, and the report of the Directors was taken as read.

The CHAIRMAN: I must ask you to excuse me to-day if I am not over clear, because I have rather a sore throat, which renders it a little difficult to explain matters as one would like to do. In referring to the accounts for the half-year we will first of all, as usual, deal with the receipts. They amounted to £79,370, and they compare with £84,022, showing a decrease of £4,648. I will remark upon the question of the traffic a little later, and will pass on to the expenses, which amounted to £43,424, compared with £39,140, showing an increase, apparently, in one sense, of £4,285. Well, it appears, on the face of it, somewhat unsatisfactory that there should be a decrease in revenue and an increase in expenses, but I think I shall be able to show you before I have gone very far that that points in one respect to a very satisfactory position in your affairs, and considerable improvement in the stability of your Company. I do not know whether you would like me, as usual, to go through all the items making up those figures. I shall have pleasure in doing so if you like, but as respects more particularly the staff expenses I cannot throw any light upon the position, because you are all aware of the reason why there is an increase in those expenses; and they account for £1,881 out of the increase, leaving only a difference of £654. That again is pretty well accounted for by the fact that we sent out stationery to the amount of £576 more. This is always a variable item, and, as I have explained before, we send it out in large quantities in order to avoid the recurring expense of carriage, &c. The indents were particularly large last half-year, and as a matter of fact, a lot of that stationery remains. You have to work it off, and that consequently means that we shall be spending somewhat less in this direction in connection with demands coming forward in the next few months. Apparatus accounts for an increase of £42, which is ascribable to the new lines; and travelling expenses account for about £54 more. There you really have the whole of the increase in these items. In other respects there has been a little economy, but I do not know that I need labour these figures any more. Then comes the question of the ships. On the question of the staff, of course, the new scheme, so to say, is in operation—the cables are now laid and being worked. With respect, however, to the ships, that is not the case. The changes were all going on in the last half-year, and for a time we were compelled, in carrying out the policy of the company to have three ships on the station in order, ultimately, to be able to do with one ship. On the "Norseman" there is a decrease of £1,038, because she was taken out of commission on the 13th of March. There is a slight increase in her coal. On the "Viking" there is an increase of expenses, because during the corresponding period she was out of commission for a considerable period, and that makes £1,735 on that account. On coals in the case of the "Viking," there is an increase of £341. Then come the items of the new ship, including her fitting up, &c., £4,205, and coal £769. The total result of the reductions and the increases is an advance of £1,845. With respect to Abstract "C" there was a considerable diminution of expenses. Abstract "C" deals with the expenses in London, and there is a saving there of some £230. That is satisfactory to you, I know, because you always look very narrowly at the London expenses, and therefore abstract "C" comes out all right. Of course, both with respect to the staff and with respect to these ships these figures, although, as I began by saying, somewhat unsatisfactory in themselves, embody the result of a policy which has been that of the shareholders as well as that of the Board, and I think that in view of that fact we ought just to look at the position which has been brought about. Now, what was the object with which these loop cables were laid? It was to avoid interruptions, to keep the traffic together by preventing interruptions—I will refer to this later on—and to enable us ultimately to do with one ship. You will observe from the report that these objects have been secured. There has been since these cables were completed between Pernambuco and the River Plate not one single interruption. You may remember that we said to you when we recommended this policy that the interruptions would be very much less by its adoption—that you would probably not suffer from so many; but on this particular occasion I am very pleased to say that you have not suffered from any. Then there is at present, and has been now for some little time, only one ship in commission on the South American coast. Therefore the policy as respects the ships, as far as we can see, is also a success. Having, however, achieved these two points—having successfully carried out your policy with respect to the ships and the interruptions—we ought to look a little further. In providing the loops and the duplex of the new cable, we had, of course, certain objects too, and those objects were to enable us successfully to meet the numerous competitors that were in the field, to do our work well, and to hold the traffic together. Well, it would be manifestly useless to have an additional cable, with a duplex arrangement—which practically makes three circuits instead of the one originally—without providing the staff to meet them, and consequently the staff had to be provided, and therefore the expenses on that account were increased. Now, have we held the traffic together; have we succeeded, without more damage than might have been expected, in facing these various competing lines, which at one time appeared to be springing up from every quarter of the globe almost? Well, the work has been done in such a satisfactory manner—I do not mean to say it is from that fact alone—but the work has been done in such a manner that there is not only no diminution in it, but, with all this competition, we have actually 12½ per cent. more words. It is quite true that the 12½ per cent. more words has produced less money owing to competitive rates, because the rates have had to be lowered owing to the shifting of the traffic and the bad exchange. All of you know that a milreis is now worth about 10½d., instead of, at par, 27d. That is a considerable difference, and it is a thing we cannot avoid. But let us look a little further. I daresay that you are thinking, "We have spent a great deal of money but we are not getting any dividend." Well, I quite admit the reasonableness of the idea, but let us follow it out a little further. Let us suppose that these measures had not been taken, and that you were richer by the reserve fund, what would have been the position? Why, all these causes for the diminution not merely of your receipts but of your traffic would have remained. You would not have averted one of them. You would still have had all this competition; only if you had been weak you might have had more of it. In addition to that you would have had the same exchange. But you would have had a good deal worse, which we used to suffer from when we got no dividend at all, and when the position of things was so precarious—that is, the total interruption from mechanical causes of your line. Your line being only a single cord, if it were broken in one point, beyond that point you could get nothing and send nothing, and therefore the loss would have been very great indeed. You would have had a smaller share of the traffic, and your position would have been worse than it now is in every respect. I have seen an analysis in a newspaper of the accounts—evidently inserted by a friendly critic—of one of these opposing companies. Well, that opposing company has not been able to earn sufficient money to pay its expenses, and it went back, either last half-year or the half-year before it, by something like 76,000 francs, and it is not making provision to meet accruing liabilities—providing amortisation funds, and so on. This is pretty much what we ventured to forecast. We said that some of these concerns might damage existing interests, but that they would not benefit themselves. That is an instance in this case of our accuracy. Of course, the shareholders there whose money was secured for such a speculative venture are not alone getting no return for it, but they see their capital dwindling away and the liabilities on their debentures, &c., coming forward. Our position is this: that we have retained our traffic, increased it, in fact; and we only need a restoration of order—I will not say peace—in Brazil, for the encouragement of enterprise and the probable establishment of exchange upon a reasonable footing, to become again a remunerative enterprise. You see what you have lost. Independently of all these political matters—the exchange, and so on—the only thing you could lose would be traffic, but you have not lost it. On the contrary, you have had an increase, as I have said, of 12½ per cent. Therefore, as far as the working of the concern goes, it has been quite as successful this last half-year, only that the work it has done has not produced the same money. The shareholders are aware, as everyone is, of the troubles in Brazil—I am speaking now more particularly of the current half-year; and what has occurred throws rather a strong light upon the recommendation of the Board that there should be no dividend. During the current half-year message work was entirely suspended on our lines by the Government of Brazil from the 6th to the 18th of September. That suspension was then withdrawn with respect to messages in plain language. I need not, however, tell you that when merchants and others who have arranged the whole of their business for about 25 years upon the system of coding—which has been the universal telegraphic language of the world—when they are told suddenly (because no notice

Digitized by Google

whatever was given of this), "You cannot send any more code messages," such an intimation must very much impede the transaction of their business, and must very much discourage telegraphic communication. Following upon that again, the Government prohibited communication with the Santa Catarina office in Brazil. Later on the Mello Party got possession of Santa Catarina, and they were so obliging as to seal up our office and the instruments. Then, only yesterday, I am sorry to say we got another notice—namely, that the Government of Brazil had suspended communication between Pernambuco and Rio for internal Brazilian messages. That last bit of news had not come at the time of our decision as to dividend; but, in face of our knowledge of what had occurred previously, I think you will all agree that under such circumstances, if the Directors, who call themselves men of business, had "stretched a point" —although Directors are always anxious to please shareholders—they would on this occasion have been very severely to blame. The present state of things throws an extremely lurid light on possibilities. These suspensions of communication that have taken place might go further, and we might be, without the power to hinder it, in this position—that we should have practically no revenue, and that our expenses would be going on. Well, you know we had our reserve fund, but you are aware that that has gone into cables, shipping, and various things, and, therefore, that is not available, and the only thing that is available, in the event of anything of this sort occuring—though I fervently hope that nothing of the kind will take place, although it is not in our power to prevent it—but in case of anything of that sort occurring, the only safety you have is in the money we have got in reserve. We have £19,000 to guard us against the contingency of a total absence of revenue. I do not think I need say one more word on that point, because I am satisfied—at least I hope it is so—that you will agree with me. Our Company is not in a position to be able to save itself from all these causes and consequences. We have laid cables in Brazil and we are there. If Brazil is at war, if she has a revolution, if any of these unpleasant things occur, we cannot button up our coats and walk off and say it is no concern of ours. We must do our best to make the position as little hurtful as we possibly can. You heard what I have said about interferences with our cables in the current half-year, and you will see from that that there is a great probability of our doing worse. I like to be always plain and open with you, and that you should know as much as I do about your position. You will have gathered from what I have said that the receipts are not so satisfactory, and neither are they. If they go on at the present rate they show that we shall be £9,000 worse off than we were during the half-year I am now talking about, so you see that for the moment, until there is a great change in the political position in Brazil, your position is not a satisfactory one. The key note of our position is the political position in Brazil and the state of the exchange. If those evils are cured, *ipso facto*, with your existing traffic, you would be doing exceedingly well. It is nothing else but that. There is one little gleam of sunshine—it rather regards the future than the present. You know that the cables which have been laid have not exhausted the competitive schemes by which we were surrounded. There was still one of them left, and a formidable one—the project to lay a cable from Rio direct to the River Plate, so as to tap all our Brazilian trade. I am pleased to say that that is averted, and we have got the boot put on the other leg. If there is to be such a cable laid at all we are to have the first chance of constructing it; but no cable is to be laid unless it can be proved that the Government lines, which are working in the interior of Brazil, and the lines of this Company are absolutely inadequate to carry the traffic, a position which will not arise, I think, for a good many years. No such line as that is to be laid, however, except in that eventuality. We have done that for you, and that excludes the only line, as far as I can see, by which we were threatened. I therefore hope that we have bottomed these competitions, although we cannot make an absolute statement on the point. I think I ought now to say a word about our staff. You know, of course, that they are eminently men of peace, engaged, as they suppose, in a peaceful avocation, and doing peaceful work. Well, it is a little alarming to such men to find shells exploding in front of their office doors; it is a little alarming for one of them to be hit, and to feel that the bombardment which produces these effects is going on from day to day without his knowing what its results may be. I am sorry to say that we received a telegram a few hours ago to say that one of them, a porter, had been killed by a stray shot. I think that, under the circumstances we ought to feel that these men have done very well in sticking to their posts, and that, without concerning ourselves with any formal resolution, they deserve an expression of the feeling of the meeting. (I am very pleased to hear that intimation of your approval.) There is not very much more for me to say. I made a note to say that our affairs are wrapped up with the prosperity of Brazil, but that is a truism. With respect to the new ship, she works exceedingly well, and has already rendered us eminent services, which go far to repay a considerable portion of her cost. We have every reason to anticipate, from our experience up to the present time, that this ship will be capable of keeping our system in good order without the assistance of a second ship. There will therefore be an economy in the working of that department. The "Norseman" will settle down presently; we shall ascertain her lowest working cost, and shall bring that to bear. Then, after the 31st of December, when the transition period ceases—because there were certain engagements which could not be got rid of at twenty-four hours' notice—there will be a considerable saving in certain expenses connected with the other two vessels, the lying up of which in dock will cost us little. As respects Brazil, our service there, as you may judge from what I have said, is rather exceptional. We do our utmost to keep expenses down there, but what with the exceptional climatic character of the coast, and the expensive regions we have to do our work in, the expenses are higher than we like to see them. We keep them as low as we can, however, and we shall continue to do so. I think I may now conclude by moving—

"*That the Report and Accounts to June 30, 1893, now submitted, be and are hereby approved and adopted.*"

Mr. C. W. EARLE seconded the resolution.

Mr. PETO stated that he had attended many of the meetings of the Company, and it had nearly always been his pleasure to express his satisfaction with the accounts. On the present occasion, however, the non-payment of a dividend had come upon them with very great disappointment. So far as he was personally concerned, he spoke quite disinterestedly, as he held only Deferred shares, but he represented a large number of holders of Ordinary and Preferred shares. The payment of no dividend in such times as these was very hard on those people. He agreed that the position of the Company was very much better than it ever was before, and he recognised that the Directors had had a very anxious time. It was in no hostile spirit that he proposed an amendment to the effect that a dividend of 3s. a share, free of income-tax, should be paid for the half-year ended June 30th.

Mr. ENNIS seconded the motion, and ventured to think that the views expressed by the Chairman might be too pessimistic.

The CHAIRMAN pointed out that the amendment was inadmissible in the form in which it had been put.

The SOLICITOR stated that according to the Articles of Association no larger dividend could be declared by the meeting than that recommended by the Directors.

The CHAIRMAN said that the Directors had very carefully deliberated on the subject, but, although they were most desirous of declaring a dividend, they felt that, as prudent men, they could not do so. It had been said that his remarks had been unduly pessimistic, but he thought that that could not truly be said in view of the fact which he had pointed out, that the Government had actually stopped their whole lines. He might state that they had received considerably more proxies on the present occasion than they did last time when they paid a dividend. Reference had been made to the value of the continuity of dividend, but there was something a good deal more important than that, namely continuity of communication and continuity of credit. If they paid the dividend suggested, and found out that they had exceeded their margin, they might have to borrow money, supposing they could do so. But what was to be the condition of things in Brazil a day, a week, or a month hence? and how were they likely to be able to borrow money if the state of things was such that people coming to the Company's offices found that they could not send a message? Having very carefully considered the whole question in conjunction with the other Directors, and including their latest member (Mr. J. Coppen)—having all of them given the utmost consideration to the question—they deliberately, although reluctantly, came to the conclusion they had arrived at. The shareholders, as business men, must know that the Directors—who were in no way responsible for the existing state of things—were doing the very best they could.

Mr. FRY suggested that the sum of £5,000 should be put to the reserve fund, and that a larger balance should be carried forward.

The CHAIRMAN stated that there was no power for the shareholders to act upon such a proposal. The money had been put to the reserve fund by the Directors and could not be taken out.

Mr. FRY afterwards contended that the Directors ought to reduce their fees, and that the Managing Director's remuneration was too heavy. He objected altogether to managing directors in telegraph companies. The Directors' qualifications ought also, he argued, to be increased.

The CHAIRMAN stated that no board of directors that he was acquainted with had a larger holding than the former Directors of this Company when it was on the high road to the Bankruptcy Court. He had never yet found—and there were reasons which told the other way—that very large shareholders were the most fitting men to put on boards as directors. He regretted that the discussion seemed to imply that the directors were not doing their best, although the policy which had been proposed and approved by the shareholders had all been carried out, with results successful in every direction. In answer to Mr. Dyett he added that no Director of the Company held less than his qualification, according to the Articles of Association. The clause in the Articles dealing with this matter was not the present Directors' clause, it having been proposed by their predecessors, who had the enormous holdings he had mentioned, and under whose management the Company was going rapidly to a very unpleasant place.

Mr. FRY: Would it not be a good thing to have this clause altered?

The CHAIRMAN: There is not the least objection to that.

Mr. BAKER also complained of the non-payment of a dividend in the present dreadful state of things, financially. If the Directors did not think that a dividend could be paid they ought, he held, to set about reducing expenses. He did not think that a managing director was wanted at such a heavy salary.

Mr. JOHN COPPEN addressed the meeting at some length and warmly defended the action of the Directors in not declaring a dividend. They very much regretted this course, but they were not philanthropists, and must look at the question from the hard standpoint of business. The remarks regarding the Directors' remuneration could not have been made at a more unfavourable time than the present. It was absolutely necessary for them in their business to have a managing director, who had most responsible duties to fulfil, and who, like the Secretary, and all the Directors, had done their utmost for the Company.

The CHAIRMAN stated that Major Wood was a most efficient, zealous and able officer.

Major WOOD (the Managing Director) reminded the shareholders of the former position of the Company, when Mr. Cunningham and himself had to "back" its bills to keep the Company from going into bankruptcy. He had rendered them valuable services in the past, although he was aware that he had made himself unpopular with certain gentlemen, whose business it was to buy and sell shares, owing to his openly

Digitized by Google

expressed regret at the high prices which some persons in the past had paid for the Company's shares.

The resolution on being put to the meeting was carried with a few dissentients.

On the motion of Mr. ENNIS, seconded by Mr. BAKER, a vote of thanks was passed to the Chairman, and the meeting then terminated.

Electric Construction Company (Limited).

The Statutory meeting of this Company was held yesterday (Thursday), at the Cannon-street Hotel, Sir Daniel Cooper, Bart., presiding.

The SECRETARY (Mr. James Gray) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, this meeting has been called in compliance with the provisions of the Limited Liability Companies Act, which directs that a meeting of the shareholders be held within four months of the registration of the Company, and we have no formal business to submit to you; but we are glad to have this opportunity of informing you as to the position of the Company. I will do so generally, and our Managing Director (Mr. Garcke) will give you some further information as to the business we are doing, and how the work is going on at Bushbury. I am happy to inform you that the reconstruction of the old Company into the new has been carried out with complete success. Practically all the debenture-holders of the Corporation have accepted corresponding debentures of the Company, and the Directors feel obliged to them for their confidence, which I believe they will find has not been misplaced. As regards the shareholders, only two holders of 55 shares decline to accept the new shares instead of the old, and the reconstruction may, therefore, be said to be complete. We have applied to the Stock Exchange for a quotation for the new shares, and, as we have supplied them with full and, as we believe, satisfactory information on all points, we hope that the quotation may soon be granted. Then we have succeeded in re-establishing the credit of the Company, and are in consequence able to do business on more advantageous terms than was possible in recent years. We have therefore, so far, every reason to expect that we shall be able (next autumn) to submit a satisfactory report to you of the year's transactions. Since our last meeting the Board has been strengthened by the addition of Mr. Philip Edward Beachcroft, who on our invitation accepted a seat at the Board. He represents the Trustees of our First Mortgage Debentures and also large holdings of shares. Mr. Garcke will now give you some information respecting the business of the Company and the work it has turned out and is now engaged upon.

Mr. EMILE GARCKE said: I am aware that it is not necessary that I should take up much of your time on this occasion, as it is only four months ago that I made a full statement to you on the affairs of the Company. When I had the pleasure of addressing you as shareholders of the old Company on July 5th, I explained in some detail the financial position of the Company, and I gave you a description of your various assets. I told you that there was still much to be done before we should be in what we considered a thoroughly sound financial and commercial position, but I told you also that many of our investments were of such a character that, if properly developed and taken care of, they promised, not only to become more valuable, but also to have the effect of largely increasing the business of the Company. I also told you that prior to the reconstruction the Company was suffering both in name and credit, that we had difficulties in competing fairly with others, and that we did not get the full benefit of the good work we had done or were doing; and I explained that if the reconstruction were carried the prospects of the Company in these respects might be expected to improve. I now wish to indicate generally how far these anticipations have been realised in the four months which have since elapsed. The financial position has greatly improved. We have taken steps to realise some of the securities in which so much of your money is locked up, and the credit of the Company now stands on a much firmer basis. Of course these changes can only be accomplished slowly, and four months is not a long period in which to do very much in such matters, but so long as our progress is sure and on right lines, we must not complain. The business, as you are aware, was taken over from the old Company as from July 1st, and that is the date from which the profit and loss account of the new Company will start. Since then, notwithstanding the general depression in trade, we have not done badly in the matter of orders. Our orders are I believe fully up to the average of previous years, and we ought to have a satisfactory profit upon these orders, but until our books are closed I cannot speak with certainty as to the result of work still in course of execution. In discussing this question of profit it must not be forgotten that we have very extensive works equipped for carrying out more extensive orders than we have yet obtained; and we all know that when factories are only partially employed the work is not so economically done as when the plant and staff are working up to their fullest capacity, for the standing charges and expenses of management are the same, whether we do much work or little. With regard to the various subsidiary companies in which so much of our capital is invested, our policy has been to assist them into a sound position, and to do this without prejudicing the parent Company, and without adding to our responsibilities, our policy being to liquidate outstanding liabilities and to reduce our responsibilities. I mentioned to you that we looked forward to the development of electric traction with much hope, and that our investments in this direction would help us to get further business. I am glad to say there are good reasons for believing that these anticipations were well founded. The work which we have done in the field of electric traction, not only in South Staffordshire, but in Liverpool and other places, is the best recommendation we can have. Numerous engineers and representatives of local authorities have been to inspect our work, with the result that we have secured some contracts, and are at present negotiating for several others. With regard to electric traction we have acted as pioneers in this country, and having done good work, are in the best position to undertake successfully large contracts of this kind. It will interest you to know that a company has been formed in America, under good auspices, to manufacture electrical apparatus of our design. We have not put cash into this business, but agreed to assist the Company with particulars of our inventions, designs of our machinery, and to give them the benefit of our experience. In consideration of these services, they will assign to us an interest in their company. With regard to electro-chemistry, I mentioned at the last meeting what our views were of this department of the electrical industry, and I am glad to say we are negotiating with several parties for the working of some of the electro-chemical patents in which we are interested. Other people are giving their attention to this subject, but I cannot find that any of them are ahead of us. Our technical staff have been working at these matters for many years past. They have achieved success before in this branch of electrical science, and believe that in the electro-chemical inventions now developing we have some good things. In other branches of electricity I believe I am right in saying we get our fair share of orders. Of course one firm cannot be pre-eminent in everything, and I am glad to recognise the good work done by other firms. We for our part are entitled to take credit for having done a great deal to demonstrate the capabilities of electrical apparatus and the reliability of electrical processes, and my great encouragement with regard to this Company is that its technical work is sound and beyond reproach. The working of the Overhead Railway at Liverpool is a revelation to electrical engineers in this country, and the economy with which we are running the electrical cars in South Staffordshire will, I believe, suggest a new future to many tramways which at present are working with horses or steam, but without dividends. You will, no doubt, ask what bearing all this has upon your dividends, and I want to assure you therefore that while we shall do whatever we can for the commercial development of electrical science, we shall not as a Company do any work or take any contract which does not promise to yield a fair profit to you. You will recognise that in such a business we cannot give you the actual results of the four months' working, but when the time comes for closing the books and making up the balance-sheet we have no doubt that we shall be able to show you that we have made satisfactory headway, and that our operations have been carried on at a profit, but whatever the position may be you may rely on our taking you fully into our confidence, and that we will let the balance-sheet of the new Company fairly represent its position. For myself I have confidence that we shall be able to show you that we have a sound business containing the elements of success, and that with careful management and strict economy we may reasonably look for a prosperous future. (Applause)

This concluded the business of the ordinary meeting.

An extraordinary general meeting was subsequently held for the purpose of considering resolutions proposing certain alterations in the Articles of Association.

The CHAIRMAN said the alterations embodied in the resolutions were made in compliance with the wishes of the Stock Exchange Committee. The changes were simple and intended to give to shareholders more control of the Company, and the Directors were very pleased to co-operate with the Committee of the Stock Exchange in this direction. The Chairman then moved the first resolution, viz.:—

"1.—*That Article 60 of the Articles of Association of the Company be amended by substituting the words 'one-tenth' for the words 'one-fifth' in the fourth line thereof.*"

The Article will then read:—"The Directors shall call an extraordinary meeting whenever a requisition in writing signed by not less than one-twentieth in number of the members of this Company, holders in the aggregate of not less than one-tenth in amount of the capital then issued and paid up, and stating fully the general nature of the business for which the meeting is proposed to be called, shall be delivered to the Secretary or left at, or sent by post to, the office."

Mr. BARCLAY seconded the resolution, which was carried unanimously.

The CHAIRMAN next moved:—

"2.—*That Article* 135 *of the Articles of Association of the Company be amended by adding at the end of the Article the words 'and a copy of such balance-sheet and report shall be sent out, seven days previous to the general meeting, to those shareholdrs entitled to receive the same.'*"

The Article will then read—"Once at least in every year the Directors shall lay before the Company in general meeting a proper balance-sheet and profit and loss account for the past year, made up to a date not more than four months before such meeting, and a copy of such balance-sheet and report shall be sent out, seven days previous to the general meeting, to those shareholders entitled to receive the same."

Mr. BARCLAY seconded the resolution.

Mr. HANCOCK thought it a disgrace to the Directors and the Solicitors of the Company, knowing so well what the requirements of the Stock Exchange were, to allow Articles of Association to be drawn without making provision for a statement of accounts to be sent to the shareholders seven days before the date of the general meeting. In the Articles of all companies such a provision was usual, and it was not right that such an omission should have been made in this instance. He was exceedingly pleased that the Stock Exchange Committee had refused to give a quotation to the shares of the Company without such a reasonable and proper condition being provided for.

Digitized by Google

The CHAIRMAN, in reply, said almost every set of Articles were amended by the Stock Exchange Committee when an application was made for a quotation. The Company's solicitor (Mr. Harold Brown) was one of the very best solicitors in London for work of this kind.

The resolution was then put and carried unanimously.

A vote of thanks to the Chairman and his colleagues concluded the proceedings.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

ANDERS' TELEPHONE COMPANY (LIMITED).—This Company was registered, on November 13th, with a nominal capital of £10,000, in £1 shares, to acquire all the following English patents:—No. 1,637 (1892), for "Improvements in and connected with telephones"; No. 5,712 (1892), for "Improvements in and connected with diaphragms of telephones"; No. 12,528 (1892), for "Improvements in telephonic apparatus and switches"; and No. 20,610 (1892), for "Improvements in telephonic circuits": to acquire, develop and turn to account other patents and inventions connected with improvements in telephones or telephonic apparatus, telegraphic apparatus, electric lighting, &c.; and to carry on the business of electrical engineers, and manufacturers of, and dealers in, telephones, telephonic apparatus, electric lamps, &c. The signatories (with one share each) are:—M. F. Barthelness, 158, Fenchurch-street, E.C.; J. Limberger, 83, Underhill-road, S.E.; G. Francke, 106, King's-road, Camden-road, N.W.; W. Seward, 22, Haldon-road, Wandsworth, S.W.; W. Heynemann, 50, Beresford-road, N.; R. W. Hutchison, 6, Mansfield-terrace, Milwall, E.; R. H. Wedekina, Ferndale, Shortlands.

EDINBURGH TRAMWAYS COMPANY.—This Company has been registered in Edinburgh, with a capital of £125,000, in £5 shares, to enter into and carry into effect an agreement with Dick, Kerr and Co. (Limited) to undertake and fulfil the obligations of the lease in that agreement, and also to acquire and work the tramway mentioned in it, or any other tramway within the burghs of Edinburgh, Leith, Portobello, or within a radius of 10 miles of the Register House, Princes-street, Edinburgh.

MADRAS ELECTRIC TRAMWAYS COMPANY (LIMITED).—The first annual return of this Company, made up to October 13th, has been filed. The nominal capital is £100,000, divided into shares of £1, or Rs.15, each. 78,792 shares (of which 34,077 are £1, and 44,715 are Rs.15) have been taken up, of which 19,650 £1 shares have been issued as fully paid. Upon the remaining 14,427 £1 shares a call of 10s. per share has been made, while upon the 44,715 Indian shares a call of 9s. 4d., or Rs.7, has been made, resulting in the payment of £,19,544. 19s. 8d. (England £7,192. 5s., India £12,352. 14s. 8d., or Rs.185,291).

MERVEILLEUSE ELECTRIC ARC LAMP SYNDICATE (LIMITED).—The statutory return of this Company, made up to October 11th, has been filed, and shows that out of a nominal capital of £15,000, in £1 shares, only the seven subscribers' shares have been allotted, these being issued as fully paid. By an agreement dated April 20th the Company through its agent, Alfred Conder, acquired from Emilio Zaccani the invention, provisional protection (granted February 28, 1893), and all patent and other rights in respect of the electric arc lamp "Merveilleuse," in consideration of the sum of £13,000, payable £4,500 in cash, and the remainder by the allotment of fully-paid shares. By an agreement made November 1, 1893, the Company adopted the preliminary contract, and allotted shares in part payment of purchase consideration.

MIDLAND ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to October 11th, has been filed. 3,139 shares have been taken up out of a capital of £50,000, in £10 shares; 3,132 have been issued as fully paid, while the full amount has been called and paid on the remaining seven shares.

MINERS' LAMP ELECTRIC LIGHTING COMPANY (LIMITED).—The usual return for 1893 of this Company, made up to October 9th, shows that with a capital of £3,000, in £5 shares, 301 have been subscribed for, of which 190 have been issued as fully paid. Upon the remaining 111 shares the full amount has been called, resulting in the payment of £550.

NATIONAL TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to August 1st, has been filed. The nominal capital is £4,000,000 divided into 15,000 First Preference £10, 15,000 Second Preference £10, 250,000 Third Preference £5, and 490,000 Ordinary £5 shares. All the First and Second Preference, 119,234 of the Third Preference, and 484,597 of the Ordinary shares have been taken up, and 35,028 Ordinary, and 28,284 Third Preference shares have been issued as fully paid. Upon the remainder the full calls have been made, resulting in a payment of £3,002,595.

OTIS ELEVATOR COMPANY (LIMITED).—The statutory return of this Company made up to July 31st has been filed; 2,000 shares of £10 each have been taken up, of which 650 were issued as fully paid. The remaining 1,350 shares have had a call of £4 per share, resulting in a total payment of £8,100.

PACIFIC TELEGRAPH COMPANY (LIMITED).—The return of this Company for 1892, filed on October 23rd, shows that only 18 shares have been taken up out of a nominal capital of two millions sterling, in shares of £10 each. The full amount has been called on these shares, resulting in the payment of £130 and leaving £50 unpaid.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—An agreement made October 6, 1893, between John E. Condict, of Salt Lake City, Utah, U.S.A., and this Company states that the Company agrees to purchase from the vendor 5,000 Preferred and 7,997 Common shares of stock of $100 each in the Salt Lake and Ogden Gas and Electric Light Company, a concern formed under the laws of the State of New Jersey, U.S.A., and in consideration therefor has allotted to the vendor 259,940 Ordinary shares.

CITY NOTES, &c.

ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT.—The eleventh annual report of the Directors, to be presented to the general meeting to be held in Berlin on the 28th inst., commences with a review of the financial progress of the Company during the ten years it has been in existence. It was founded in May, 1883, as the Deutsche Edison-Gesellschaft für Angervandte Elektricität, with a capital of M.5,000,000, which has been several times increased until now it is M.20,000,000; and the average dividend paid, including that proposed for the last year's working, is 7·62 per cent. The report reviews in succession the progress of business at the Company's various branches and agencies, and gives particulars of the 14 electric tramways it is working or which are in progress. Referring to the Electrical Company, in London, which has been reorganised, the report says that 80 per cent. of its capital of £15,000 has been called up, and the Company is now beginning to reach the English market, which is extremely difficult to cater for. The Directors congratulate the shareholders on the prosperous condition of the Company, and propose to pay a dividend for the year 1892-1893 of 8½ per cent.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended November 12th were £909, as against £945 for the corresponding period of last year, being a decrease of £36. The total receipts for the half-year amount to £15,546, against £15,345 in the corresponding period of 1892, being an increase of £201.

COMMERCIAL CABLE COMPANY.—The Committee of Awards at the World's Columbian Exposition, Chicago, has granted to this Company the only two awards issued for improved apparatus and system of working submarine cables.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—Notice is given of the drawing of 345 £100 Five per Cent. Mortgage Debentures of this Company, for payment at par, on January 1st next, by Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C., and interest on which will cease on January 1st. The list of bonds is set out in our advertisement columns.

PANULCILLO COPPER COMPANY (LIMITED).—A meeting of this Company is to be held at Winchester House on Friday next, the 24th inst., to consider a proposal for the sale of the Company's property and under taking, and, if this is agreed to, to pass a resolution voluntarily winding up the Company.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LTD.).—The Directors of this Company give notice that they intend to renew the existing £5 per cent. Debentures which mature on January 1st next, and those which mature on January 1, 1899. Holders of the existing Debentures are requested to leave them at the office of the Company, 38, Old Broad-street, E.C., between December 15th and December 31st, and they will be exchanged after January 8th for an equal amount of new Debentures. Existing Debentures not so lodged with the Company will be paid off in cash by the Company's bankers.

THE PROJECTED CABLE BETWEEN AUSTRALIA AND CANADA.—Speaking at the meeting on the 10th inst. of the Scottish Australian Investment Company (Limited), the Chairman, Mr. F. P. Ward, stated that Mr. Sanford Fleming had left Canada for Australia to arrange for the construction of a cable between the two colonies. He had four different plans in view, which had been regarded as very much dependent on Imperial support, but he believed it was now likely that they would be able to do without such assistance. A cable was an essential condition of trade between the two colonies.

THE ZANZIBAR-SEYCHELLES TELEGRAPH CABLE.—The Eastern Telegraph Company (Limited) announce the laying and opening for traffic of the cable between Zanzibar and the Islands of the Seychelles, being the first section of the cable Zanzibar-Seychelles-Mauritius. The extension of the cable to the Island of Mauritius is expected to be completed by the end of this month. The tariff from the United Kingdom to Seychelles will be 7s. 3d. per word.

WENHAM COMPANY (LIMITED).—After bringing into account the sum of £595. 4s. 7d. from last year, the profit and loss account shows a debit balance of £1,887. 10s. 9d. The report states that the operations of the Company have not only been materially affected by the extreme depression of trade, but have also suffered from the exceptional competition of other

Digitized by Google

systems of lighting. The outstanding debentures of the Company, amounting to £17,500, become due on December 1st next. To provide for the same the Directors have decided on an issue of Seven per Cent. Debentures.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended November 10, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,316.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 810.—Vol. XXXII. FRIDAY, NOVEMBER 24, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The draft regulations for electric tramways which have been submitted for the consideration of the Board of Trade, and which we print in full in another column, are the most important of the kind since the much-discussed overhead wire regulations, and they are potentially of far greater importance. The tests to be made, and the records to be kept, appear at first to be rather alarming; but on closer examination they seem to compare favourably with the self-imposed work of any conscientious manager of an electric supply station. Tramway engineers, it is true, have not hitherto troubled themselves about such matters. They seem to be able to run their cars to their own satisfaction in some cases without any measuring instruments whatever. We do not find among the definitions any attempt to draw the line between a tramway and a railway, but that, perhaps, is settled by the Tramways Act. These regulations will, we suppose, receive the careful attention of tramway engineers, but it is quite possible that they will ignore them until it is too late, and then get up an agitation for alterations.

The accident at Manchester on the morning of the 16th inst. has afforded an opportunity for the exhibition of the extraordinary ignorance of electrical matters which is tolerated by editors of London and provincial daily papers. A journalist making mistakes of a quasi-scientific kind in descriptions of flower shows or street accidents, volunteering such statements, for example, that chrysanthemums are endogenous tubers, or that a cab collided with a lamp-post with great centrifugal force, would soon meet with his deserts; nor would literary, historical, artistic ignorance be allowed in dramatic or art criticisms. Any nonsense, however, is allowed in electrical matters. Only last week we alluded to an article in the *Daily Chronicle*, and again we find this journal distinguishing itself on the subject of the Manchester accident. "The explanation," it says, "will probably be that the copper mains were somehow carrying too heavy a current, became fused, and temporarily converted the cable chamber into something like a blast furnace."

It seems probable that the explosion, which, by-the-bye, only just raised the box cover out of its seat, was due to leakage of gas into the conduit, as at Glasgow on the 9th inst. and in several other cases. Such accidents merely arise from the presence of a conduit in a street in which leaky gas mains are laid; it is to be surmised that they are often ready to explode, and merely wait for a spark. Electric light mains are by no means essential for producing the necessary spark; an explosion has occurred in a telegraph junction box at Newcastle, and the Glasgow accident is attributed to a match thrown down by a smoker. The fault, of course, lies with the company that impregnates the soil with explosive gas, for we have as yet seen no evidence as to electrolytic evolution of gases. Soon after the explosion at Manchester the mains were short-circuited, with, we presume, the usual result of a blown fuse at the station. The flame had set fire to the insulation of the rubber-covered cables, which were united at this box to bare conductors. These were quite uninjured. The insulation having been burned away, the cables, Mr. Wooler informs us, came into contact with the iron pipe and to dead earth.

In our account of the Manchester station (*The Electrician*, Vol. XXXI., p. 614), an allusion to the plant for ventilating the conduits was made. Air is continuously circulated through them by means of a fan driven by a motor at the station. In New York a similar provision has been made, but the different mode of application is worthy of notice. In *The Electrician*, Vol. XXX., p. 471, we recorded that twelve Roots blowers are run at different parts of the subways and force air into the conduits at a greater pressure than the gas pressure in the surrounding soil. The blast is sufficient to renew the whole of the air about once an hour. The joints are made as tight as possible, and the air is compelled to make its way, not back to the station, but through such leaks as are inevitable. We hasten to give every credit to our American friends for this very ingenious device.

The letter from Mr. Steinmetz in our Correspondence column this week tends to some extent to explain his position with regard to the candle-power of search lights, and brings out, as Mr. Nerz has done, the interesting theoretical fact that when the source of light has a finite size the beam diminishes in intensity as the square of the distance. As is generally the case in long discussions, the disputants have been writing about different things, and we admit that our reference to a beam of parallel rays does not bear upon the point which Mr. Steinmetz now emphasises. But the discussion originally related to the actual photometry of search lights, and not to theoretical reflectors. In practice, the angular divergence of the projected beam of light depends not only on the size of

Digitized by Google

the arc, as compared with its distance from the reflectors or projecting lenses, but also upon any irregularities in the latter which tend to prevent them from sending off all the rays in a truly parallel beam. In the former case, as our correspondent points out, the divergence commences at the projecting surface, but is not the same for all parts of the surface. In the latter case the spreading of the light follows a different law altogether.

It cannot be assumed that if the path of the rays be produced backwards, through the projector, that they will meet at a point. The diagram (Fig. 4) in M. Nerz's article, *The Electrician*, Vol. XXX., p. 714, shows that a cone of rays starts from each point on the surface of the reflector. Not only are these cones necessarily of different angles, decreasing towards the periphery, but if the rays are produced backwards, they will begin at once to diverge again, and will not intersect at any particular point on the axis. So long as the axes of these cones are strictly parallel, the surface of the reflector may, as Mr. Steinmetz contends, and as M. Nerz proves in the second part of his article, be considered as a luminous surface of nearly the same brilliance as the crater. So long as this condition is rigidly maintained, it is permissible to speak of the photometric candle-power of the search light along the axis. But a very small convergence or divergence of the axes of the cones, whether by incorrect focussing, or by imperfect figure of the reflector, at once renders meaningless the photometric measurement as well as the photometric designation of the candle-power of the search light. The candle-power of the beam will depend on the divergence of the rays, and this can be altered in several ways without affecting the total quantity of light which is given out, and which after all is the really important thing. With an ordinary light the candle-power is proportional to the quantity of light given out. We are dealing, practically, in the case of projectors, with a mixture of light sources; and we think it highly improbable that any three photometric measurements of candle-power of a search light at different distances along the axis would be found to agree.

We print this week an interesting article by M. Abdank-Abakanowicz on the subject of compensating electrical instruments for hysteresis effects. A device, due to Mr. Evershed, for the same purpose was recently described in our columns by Mr. E. B. Vignoles, and it will be observed that there is a great similarity between the two methods. In each case the greater retentiveness of a steel core is used to neutralise that of the iron. There are, however, differences between the two systems of compensation. Mr. Evershed uses the magnetism of the steel to destroy the remanent magnetism of the iron; while in the other method the magnetism of each is retained, and so utilised that their effects on the moving parts of the instrument neutralise each other. The former method seems much simpler, and the compensation may be quite sufficiently good, but the latter is likely to secure far more perfect compensation.

One of the numerous drawbacks to the practical realisation of the thermo-dynamic beauties of the internal combustion engine is the frailty of the materials of which this engine has, in its present mode of action, to be built. The useful working of a piston in a cylinder is inconsistent with a temperature approaching red heat, and it becomes necessary to rob the working substance of the greater part of its heat, almost as soon as it is generated, in order that the engine may be preserved in a state in which it is capable of doing any work at all. But there are differences of opinion as to the most satisfactory way in which this large amount of heat may be abstracted. The most obvious, and absolutely inefficient way, is to follow Lenoir, and place a water jacket round the cylinder containing the working gases. A common improvement on this consists in the prior compression of these gases inside the cylinder, thus reducing the surface of cylinder wall per pound of fuel consumed per explosion. Even this, however, was found, in the Society of Arts trials, to result in the abstraction of 52 per cent. of the heat in useless jacket warming. Another mode occurs in the well-known "Atkinson" cycle, in which the gases are exploded and expanded to several volumes very rapidly, being passed through the cylinder too quickly to give up much heat to the walls, but retaining a large proportion of unused heat in the exhaust.

The latest attempt to prevent excessive cylinder heating is the result of a suggestion by Dr. Pröll, in which it is proposed to abolish the cooling by water and to put in its place a cooling agent by expanding compressed air. The suddenly generated heat of the fuel gas is largely absorbed by the expanding compressed air, the useful activity of the latter being thereby increased by the heat which would ordinarily pass into the water jacket. The ordinary compressed air is used only, of course, where there is such a system available. In other cases an auxiliary compressor would be necessary, and would absorb power. The net advantage of the compressed air would be the difference between the power thus absorbed and the power developed in the heated expander. It is impossible to comment further upon this system, which from a theoretical point of view is commendable, until further details as to the mode in which the expanding air is heated are forthcoming. We presume the compressed air is retained in a separate chamber from the fuel gas, otherwise the combustion would be imperfect; and, if so, the whole practicability of the scheme must depend on the arrangement of these two chambers.

The attack made the other day upon Major Wood at the Meeting of the Western and Brazilian Company is no doubt accounted for by the non-payment of a dividend, owing to the state of affairs which has existed for some time in South America. The suggestion to get rid of the Managing Director, so as to save his remuneration, was ill-considered, and showed that the gentlemen who made it evidently possessed very little knowledge of the subject, or they would not have advocated such a change in the management. Major Wood replied with considerable spirit and effect, and showed that he thoroughly understood the details of the Company and its management, as well as how necessary it was that himself or some equally-competent man should

Digitized by Google

occupy the position. Submarine telegraphs require very careful and constant attention; they have become an important factor in the political, commercial and social world, and it is clearly necessary that men of the highest character and ability should be responsible for their management. These undertakings cannot work themselves, and if the views of the gentlemen who attacked Major Wood were carried out it would, we think, very soon be found that chaos would exist where at present order prevails.

Cable Interruptions and Repairs:

	Dates of Interruption.	Date of Repair.
Perim-Obock	November 10th.	November 17th.
Cayenne-Paramaribo	October 25th.	—

The Telephone at Cardiff.—The National Telephone Company have made arrangements at Cardiff and Penarth to keep the Exchange open continuously day and night, including Sundays and holidays.

Technical Education.—Mr. Acland, Vice-President of the Committee of Council of Education, on Saturday last laid the foundation stone of the new Technical School, which is being erected by the Corporation of Birmingham at a cost of nearly £50,000.

Fire at Electrical Works.—A large five-story factory, formerly in the occupation of Blakey, Emmott and Co. (Limited), and now supplying some Halifax shops with electric light, was burned out yesterday morning. A gable fell out on to the residence of Mr. Emmott and demolished a great part of it.

Bristol.—Last Monday evening the arc lamps on Bristol Bridge and down Victoria-street were lighted, this being the beginning of the permanent street arc lighting in Bristol. The gas lamps have not yet been dispensed with, as for a few evenings the electric light will cease at midnight.

Cable Extensions.—The Eastern Telegraph Company announce the laying and opening for traffic yesterday of the Mauritius cable, thus connecting the Islands of the Seychelles and Mauritius with Zanzibar and the Company's general system of submarine telegraphs. The through tariff to Mauritius from the United Kingdom will be 8s. 9d. per word.

The Phonopore.—We are informed by the Phonopore Company that it has happened lately on four different lines that whilst the ordinary telegraph could not work, on account of a breakage of the wire, messages were sent by the phonopore just as if nothing unusual had taken place; the currents by which the phonopore is worked jumping the gap at the breakage.

Appointments Vacant.—The governors of the Battersea Polytechnic Institute invite applications for the appointment of teachers of the various evening classes from January to May, 1894. Particulars appear in our advertisement columns. ——An experienced master is required to take charge of the Physics section of an important modern school in the South of England; further particulars appear elsewhere.

A Self-Recording Target.—A self-recording target which is being exhibited at the Drill Hall, Plymouth, is exciting much local interest. The face of the target is composed of steel, and the various rings are all separate. When the bullet reaches the target the ring on which it strikes gives way, and is forced forward again by a spring. The backward motion of the ring closes an electric circuit actuating an indicator at the shooting point.

The Montefiore Electro-Technical Institute.—On Thursday last week the King of the Belgians went to Liége to inspect the Electro-Technical Institute, founded by Senator Montefiore-Levi. The rector explained the origin of the Institute and the difficulties which had to be surmounted in founding it. Four hundred electricians had, he said, been trained in it. This year there were 75 students, two-thirds of whom were foreigners.

Lamp-Holders.—We have received from Mr. W. J. Jenks, of New York, a copy of the "Complainant's Proofs" in a lampholder patent infringement action which is being brought by the Edison Company of America against the Electric Engineering and Supply Company. Amongst the patents said to be infringed are the American equivalents of the Edison (1880) and Johnson (1882) patents held in this country by the Edison-Swan Company.

Brussels.—The Brussels central lighting station was at last formally opened at the beginning of the present month. The work was, it may be remembered, entrusted to the India-Rubber, Gutta-Percha and Telegraph Company. The station is of 40,000-light capacity, and is on the low-pressure sub-station system. The plant will be run from sunset till midnight, after which current will be furnished to the consumers by the accumulators, which are of the Julien type. The system of street-wiring employed is that of insulated cables in cast-iron tubes.

Obituary.—The death is announced of Dr. Wm. F. Hutchinson, who died suddenly in Providence, U.S.A., on September 30th, of organic disease of the heart. Dr. Hutchinson, who was 55 years old, was well known as a leading physician in Rhode Island, and as a specialist in electricity. He was an able writer, and besides contributing many articles on electromedical subjects to the medical journals, was also the author of "Practical Therapeutics." To Dr. Hutchinson is also due the discovery of the local anæsthetic effect of the "Faradic" current when the number of interruptions of the "Faradic" coil correspond to a certain pitch.

Cheltenham.—Col. J. Ord Hasted, R.E., of the Local Government Board, held an inquiry last week relative to an application by the Cheltenham Corporation for sanction to borrow £16,000 for the purpose of electric lighting. The scheme is to be carried out on the alternating system. There was strong opposition to the scheme on the grounds that the expense ought not to be incurred; that the estimate of the cost was not sufficient for all that the scheme would lead to; and that the ratepayers had not had sufficient opportunity of discussing the question. The inspector promised to submit these representations to the Local Government Board.

The Edison Lamp Patent in America.—The expiration of the English patent on the Edison lamp will not, says our New York correspondent, affect the American patent, as the date of the latter is January 27, 1880. According to the Federal Courts the life of an English patent is to be computed from the date when it is sealed, and not from the actual date on the patent; in the present case the former is May 10, 1880, and the latter November 10, 1879. The law on the subject is that the life of a domestic patent is limited by that of foreign patents granted previous to the issue of the American patent, and as a consequence the Edison lamp monopoly will expire with the Canadian Edison patent on November 19, 1894, instead of January 27, 1897, the natural limit.

Science Examinations.—In answer to a question in the House of Commons last week, Mr. Acland stated that second-class passes in the elementary stage of all science subjects were abolished by the Science and Art Department after due notice given in the time of the late Government, the object of the change being, as explained at the time, the encouragement of more advanced instruction, for which increased payments were offered. He saw no reason to believe that this action would in any way impede the progress of sound technical education, while, on the other hand, it would afford a salutary check on a good deal of instruction of a kind which it was not, on the whole, desirable to assist. Under the circumstances he could hold out no hope of the revival of second-class passes or of an alternative scheme.

Strike of Italian Telegraph Clerks.—The telegraph clerks at Milan, following the example of their colleagues in Rome, have gone out on strike. Their places have, however, been filled, and the service is therefore not interrupted. There is also a partial strike among the telegraphists at Venice. The telegraph clerks at Naples also left their posts for a few hours, but then reconsidered their decision and resumed work. At Turin, where nearly all the *employés* have joined the strike, the service

Digitized by Google

is being carried on by men from other Government departments. It has been decided to immediately recall a certain section of military telegraph operators who are now away on furlough, and to dismiss all *employés* who have in any way instigated the strike. The Ministers at the same time intimate that they are prepared to deal with all strikers who fail to resume their duties within twenty-four hours.

Royal Society.—The following Papers were down for reading yesterday:—Prof. Lockyer, on "The Photographic Art Spectrum of Electrolytic Iron;" Prof. Thorpe and P. L. Gray, "Magnetic Observations in Senegambia;" Dr. Hopkinson, E. Wilson, and F. Lydall, "Alternate-Current Electrolysis;" S. Dunkerley, on "The Whirling and Vibration of Shafts." The Royal Society's medals have this year been adjudicated by the President and Council as follows:—The Copley Medal to Sir George Gabriel Stokes, for his researches and discoveries in physical science; a Royal Medal to Prof. Arthur Schuster, for his spectroscopic researches and his researches on disruptive discharge through gases and on terrestrial magnetism; a Royal Medal to Prof. Harry Marshall Ward, for his researches into the life history of fungi and schizomycetes; and the Davy Medal to Messrs. J. H. van't Hoff and J. A. le Bel, in recognition of their introduction of the theory of a symmetric carbon, and its use in explaining the constitution of optically active carbon compounds.

Liquid Air.—In connection with the forthcoming lectures at the Royal Institution on "Air, Gaseous and Liquid," it may be mentioned that Prof. Dewar has successfully conveyed a considerable quantity of liquid air from London to Cambridge. The liquid air was carried in one of the double-glass, vacuum-jacketed flasks, the space between the inner and outer flask containing nothing but extremely attenuated mercurial vapour, together with a little liquid mercury. On pouring liquid air into the inner flask its outer surface is rapidly covered with a mercurial film of extreme thinness, forming a reflecting surface highly impervious to radiant heat. As soon as this is formed the whole apparatus is packed in solid carbonic acid, which at once freezes the liquid mercury, arrests the deposit upon the mirror, reduces the mercurial vapour to an infinitesimal quantity, forms an almost perfect vacuum, and supplies an envelope 80deg. below zero. Thus protected the liquid air reached Cambridge. The protective power of the high vacuum and the mercurial mirror will be better appreciated if it be borne in mind that the difference of temperature between liquid air and solid carbonic acid is the same as between ice and boiling water.

Telegraphy Extraordinary.—The following is a characteristic instance of the amount of energy which is devoted on the other side of the Atlantic to the rapid propagation of news. On the day of the race deciding the struggle for the International Yacht Cup, a violent storm broke down all the telegraph lines between New York and Chicago. When the evening came, the New York manager of the United Press was in possession of lengthy descriptive accounts of the race, but he had not the slightest idea of how he was going to get through to Pittsburg or Chicago. At 10.30 he went to the Long-Distance Telephone Office, and induced the officials there to do their best to get through. They got through to Pittsburg soon after 11 o'clock. A telephone message was sent to Pittsburg to hunt up a Morse instrument, and a man to work it. Meanwhile a Morse instrument was attached to the New York end of the line. At midnight all was ready. The manager of the United Press then telegraphed to Pittsburg, asking them to telephone to Chicago asking that office also to secure a Morse instrument and an operator. At Chicago, however, there was some difficulty in doing this. Finally the news was transmitted to Chicago in the following way:—At Pittsburg a telephone transmitter was placed over the Morse sounder, and at Chicago a telegraph operator held a telephone receiver to his ear with one hand, writing out what he heard in the receiver with the other hand. Transmission began at 12.30, and by 2.30 3,000 words had been sent through about the yacht race and other matters.

A 1,000-H.P. Electric Locomotive.—The following are some additional particulars with regard to the 1,000-H.P. electric locomotive, described briefly on page 32 of our issue of November 10th, which is now being constructed in America to the designs of Messrs. Sprague, Duncan and Hutchinson. The engine, says the *Electrical Engineer* of New York, is intended for switching purposes and slow-speed freight traffic. It is carried on a steel frame supported by eight coupled wheels, each 56in. in diameter. Each axle carries the armature of a 250-H.P. motor, whilst the field-magnets are supported by the axle-boxes. The armatures in question are 31in. in diameter, and have 237 coils. The motors are compound wound, and are designed to take a current of 250 amperes at 800 volts, their normal speed being 225 revolutions per minute. The four motors, when working at their maximum power, are expected to exert an effective pull of 30,000lb. on the drawbar. The connections to the motors are made through a contact cylinder, which permits them to be arranged, either all in parallel, all in series, or partly in series and partly in parallel. In changing over from one arrangement of contacts to another, resistances are first thrown in, the change is then made, and the resistance finally switched out again. This contact cylinder being of large dimensions is operated by air pressure, though hand gear is also fitted. The air is taken from the brake tanks, which are kept charged by an automatic electric pump. The reversing switch is separate from, but interlocked with, the contact cylinder in such a way that it can only be operated when the current is cut off from the motors. Provision is made for two trolleys above the car, to collect the current from the line. The total weight of the motor will be 120,000lb., so that if a drawbar pull of 30,000lb. is expected, an adhesion of one-fourth will be required. To insure as high an adhesion as possible the coupling-rods between the wheels are double-jointed, and equalising beams are used between the springs supporting the frame of the car. The total wheel base is 15ft. only, leaving only 4in. clearance between the wheels. The outer wheels only are flanged.

Blackening of Incandescent Lamp Bulbs.—I have repeatedly noticed (writes Mr. W. Stuart-Smith in the *Electrical World*) discussions as to the cause of blackening of incandescent lamp bulbs. The latest theory seems to come from France, and is to the effect that residual oxygen in the bulb, together with that which was occluded in the filament, attacks the carbon and forms carbonic oxide, which undergoes dissociation by coming in contact with the comparatively cold glass, depositing the carbon and leaving the oxygen free for a repetition of the process. It has been some years since I have paid attention to chemical matters, but, unless I am mistaken, cooling as above would *not* cause dissociation, and the above explanation cannot be the correct one. It seems to me that a portion of the action at least *must* be due to the following cause:—It is well known that all substances in the solid or liquid form give off vapour, in fact, are surrounded by an atmosphere of their own vapour. If the substance is confined in an air-tight space the vapour density is definite for every substance and for every temperature, but varies greatly with the temperature, being much greater for high temperatures. For a given substance and a given temperature the vapour density will be the same, no matter what other gases may be present; but if other gases are present in considerable quantities considerably more time will be required for the density to reach its maximum value. In a vacuum, on the contrary, the action is comparatively rapid. Carbon, when cold, is a very stable substance, and its vapour density very low; but at the high temperature of the white-hot filament, vaporisation must be comparatively rapid and the vapour density relatively great. As the hot vapour comes in contact with the cooler glass it will deposit, and thus vaporisation, instead of stopping, as would be the case if the glass was the same temperature as the filament, continues while the lamp is burning. When the lamp is extinguished the vapour in the globe must deposit on the glass until the definite density of the vapour of the cold carbon is attained. The more rapid blackening when the lamp is new may be due in part to the better condensing action of the clean glass, and it may be due in a greater part to the fact that some portions of the filament are more easily volatilised than others, and the action consequently more rapid while these are being thrown off.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(Continued from page 69.)

There is considerable difference of opinion as to whether an alternate-current armature should have iron cores or not. In the thin disc type there is no doubt that iron is inadmissible, as the armature would inevitably be drawn out of flat and jammed against the pole-pieces; but in drum and Gramme-wound machines there is no mechanical reason why the magnetic resistance should not be decreased by a liberal use of thin iron plates. But the magnetic density must be kept low or the losses from hysteresis will be serious: B_a'' must not exceed from 40,000 to 65,000. Iron cores are said to have the effect of reducing the loss from eddy currents in the copper. Regarded from a purely mechanical standing, the author is of opinion that the iron-cored drum-wound type of alternators, such as those built by the Westinghouse and the Gülcher companies, are the better adapted for power purposes. The Brush and Ferranti armatures compared with these are fragile in make, and appear to be much more likely to give trouble. The experience of Continental and American engineers seems to confirm this, and the gradual development of multiphase alternators with iron cores undoubtedly points in the same direction.

From a purely electrical point of view the Mordey alternator is almost perfect, and certainly possesses the important feature of a high efficiency of conversion at light loads—a most important consideration with some kinds of work. On the other hand, it is an undoubted fact that the light-load efficiency of many of the iron core alternators is extremely low. In designing alternators with iron in the armatures it is always important to estimate the power which will be wasted in simply magnetising and demagnetising the cores, as this will be sufficiently large to be comparable with the copper loss. Table L which is calculated for 50, 83, 100, and 130 periods per second gives the data necessary for most practical cases.

Table L.—*Power Wasted by Hysteresis.*

B C.G.S.	B'' per square inch.	Watts wasted per cubic inch. ∿ = 50.	Watts wasted per cubic inch. ∿ = 83.	Watts wasted per cubic inch. ∿ = 100.	Watts wasted per cubic inch. ∿ = 130.

18,000	116,100	1·4075	2·340	2·815	3·660

It will be noticed that for a fixed induction the waste of power increases in direct proportion to the frequency; and that for a given frequency the loss varies as the induction raised to the 1·6 power.†

The effect of the frequency on the size of an alternator for a given output demands careful attention. The frequency of an alternator is proportional to $p\frac{n}{60}$, that is, it varies directly as the number of pairs of poles in the field magnets and the number of revolutions. If the speed be fixed, the frequency determines the number of poles, and, consequently, to a large extent, the size and cost of the machine. The bearing of this point in the design of alternators will be readily appreciated on inspecting Table N, which shows the necessary revolutions per minute at the frequencies customary in this country, with various numbers of pairs of field poles.

It is seen that for a given number of pairs of poles the revolutions vary directly as the frequency, which on this account should be low. But the output of a given alternator, other things being equal, is proportional to the frequency, and therefore a low frequency means a heavy machine for the output. This is counterbalanced to a large extent because a higher induction becomes permissible as the frequency is diminished.

20	150	240	300	390

* The number of pole pieces in a machine is equal to $2p$.

The ordinary values of B_a'' are given in Table O, and are practically the same as those found advisable in the design of transformers.

Table O.

Frequencies ∿ =	Induction B_a'' = from
50	32,000 to 40,000
60	30,000 to 32,000
70	28,000 to 30,000
80	26,000 to 28,000
90	24,000 to 26,000
100	22,500 to 24,000
110	21,000 to 22,500
120	19,500 to 21,000
130	18,000 to 19,500

If the magnetic field vary in strength the induction must be the $\sqrt{\text{mean square}}$ value.

The preceding investigation of alternate-current working will be sufficient to show the modifications necessary to apply the method of designing dynamos and motors previously described. But special attention must be given to the magnetic induction, and the current density must be chosen according to the ventilation provided. For example, in an iron cored armature having a large heat waste from hysteresis, the loss in the copper must be kept relatively small, whereas in a coreless armature of the Brush or Ferranti type, the current density may be as high as 4,000 amperes per square inch, or even more. The effective pressure and current will in all cases be of chief importance, since the output, heat waste, and average torque are proportional to these values. But the maximum pressure will determine the limiting stress on the insulation, and must be considered accordingly. From this point of view the Kapp and Gülcher alternators appear to be excellent, for they give a flat top to the theoretical curve of pressure (*see* Figs. 76 and 79). Also the maximum torque will be proportional to the maximum value of the current, and the stresses must be calculated with reference to this value. In cases likely to be met with in practice both pressure and currents closely approximate to a sine law in the outer circuit, and it is also probably safe to assume that the armature pressure curve does as well; at any rate, judging from the illustrations given in Figs. 75, 76, 77, 78 and 79, the probable error is not sufficiently large to seriously affect the results. But it is pretty well demonstrated that the current in the armature coils departs widely from the simple sine function. The peripheral velocity of alternators is generally greater than that of Gramme or drum armatures, and is a question of mechanical construction. Generally, with non-magnetic core armatures of the Ferranti type, the moving parts are so light that the centrifugal strains are easily dealt with at even from 5,000 to 8,000ft. per minute. And in revolving field machines of the Brush and Brown type it is clear that the speed is only restricted by the tensile strength of soft cast iron. In revolving fields of the Construction Corporation type, since the magnets are mainly built up of wrought iron, the chief factor will be the ultimate strength of the bolts and screws holding the parts together, &c.

The estimate of the excitation presents some difficulty, but since the current is almost invariably provided by a separate direct-current dynamo, often coupled to the shaft of the alternator, a limited adjustment can be made by a variable resistance placed in series with the coils. However, it is important to notice that for every driving power there is one value of exciting current which will make the output, and, consequently, the efficiency a maximum. In fact, the output does not vary with the field strength as is the case with continuous-current machines; and it follows that a proper regulation cannot be made by the exciting current alone, but requires as well an adjustment of the driving power for each load. This is of special importance when alternators are coupled in parallel. If the exciting current be either above or below this critical value, the efficiency will be lowered and the output reduced (for the given driving power). In the first case, the armature current will be increased, and the terminal pressure also; but the efficiency will be diminished, owing to the increased loss over the armature resistance. In the second, the current will also be increased, but the terminal pressure will be lowered. But this effect is not very marked with many alternators, and in most cases the best excitation is nearly the same through the working range of output. Perhaps it is of more importance in the case of alternate current motors, for then the increase of main current may

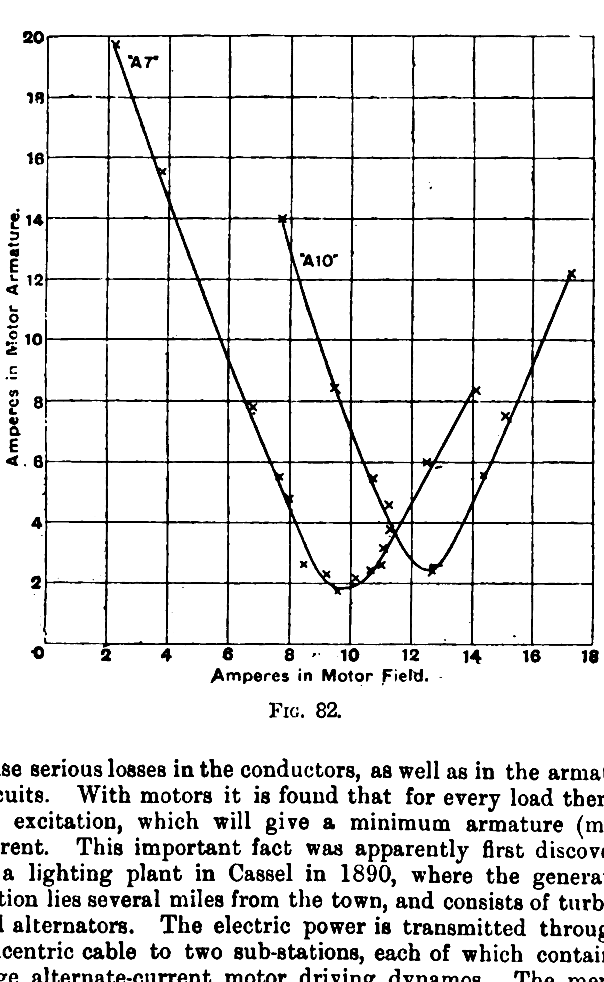

Fig. 82.

cause serious losses in the conductors, as well as in the armature circuits. With motors it is found that for every load there is *one* excitation, which will give a minimum armature (main) current. This important fact was apparently first discovered at a lighting plant in Cassel in 1890, where the generating station lies several miles from the town, and consists of turbines and alternators. The electric power is transmitted through a concentric cable to two sub-stations, each of which contains a large alternate-current motor driving dynamos. The men in charge of these machines found that the main current could be varied for different values of motor excitation. A similar effect is illustrated in Fig. 82, which refers to experiments made by Mr. Mordey with two Brush alternate motors running light. The terminal pressure was maintained constant at 2,000 volts and 100 ∿, the speed also being constant throughout the range of observation. The tests were continued with various loads, and it was found that for every output there was one value of exciting current corresponding to minimum armature current; and that the armature current rose as the excitation was increased or diminished; and that the critical excitation was approximately the same for all loads (this is partially due to the small self-induction of the machines). The terminal pressure was maintained constant throughout.

Mr. G. Kapp, Mr. Swinburne, Mr. Mordey, and others have investigated the theory of exciting alternate-current machines. And it appears that the *output* of an alternator depends on the steam admission, or simply the driving power; while the *lag*, and, consequently, the wattless current, is controlled by the excitation. And for a given brake horse-power of an alternate-current motor, the excitation determines the lag and wattless current.

The problem is complicated by armature reactions, self-induction, and capacity effects in the circuit. Armature self-induction tends to weaken the field, and therefore to necessitate more than the calculated excitation, while capacity in the armature tends to strengthen the field, and hence to reduce the value of the necessary excitation. The actual number of ampere-turns for any load will, therefore, depend on the balancing of these two effects, and no general rule can be stated. When alternators are running in parallel, with separate engines, the steam admission should be controlled by a common single governor, and not by separate governors to each engine. And the real output of each dynamo, after the throttle valve is properly set for the full output of the machine, should be measured by a wattmeter, and controlled (in accordance with its readings) through the field excitation. An ammeter is of no use for this purpose, as it gives no indication of the lag between current and pressure; and the omnibus pressure being the same for all of the machines is no criterion of the actual total electromotive force of any of the alternators. It may therefore happen that two alternators in parallel may be giving pressure differing as widely as 2,500 and 1,500 volts, and yet the omnibus pressure will show 2,000 volts, the proper station pressure, say.

(*To be continued.*)

Errata.—On p. 69 of last issue *for* $V_e = 0{\cdot}7854\ V_{max}$, *read* $V_e = 0{\cdot}835\ V_{max}$. The arrangement of poles in Fig. 76 should be such that the pairs of poles should be alternately N and S, with *similar* poles opposite one another.

THE INDIRECT CONTROL OF TELEGRAPHS BY THE UNITED STATES GOVERNMENT.

BY THOMAS COMMERFORD MARTIN.

In view of the fact that all the American telegraph, telephone, and submarine cable systems are in private hands, assumably independent of Government control, it has, I am given to understand, struck many observers in England and Europe as strange and contradictory that the Postmaster-General of the United States should dictate to any of the companies interested the terms and rates upon which they handle the Government's messages. A few explanatory words on this subject may not come amiss, especially if I shall be able to show that here, as almost everywhere else in the world, it has appeared desirable to those invested with the supreme authority, to place themselves in the position of having at their command, for moments of urgency and necessity, and with absolute right of priority and precedence, the best means of transmitting intelligence. The truth is, that in recent years, despite the principle in our constitution that the Government shall not sequester private property, at least one Postmaster-General has practised the worst form of socialistic confiscation by forcing on the companies an unfairly low rate. Compared with such a process, the conditions under which the private lines of England were annexed and converted into a public department were highly liberal and generous.

The Postmaster-General of this country is empowered by statute to fix every year the rate at which the telegraph companies shall carry Government messages. The Act vesting such power in him was approved July 24, 1866, and now is known as Title LXV. of the Revised Statutes of the United States. Discussions in Congress as to Government telegraphs are nothing new, and this Act was practically a compromise that quieted those who were supposed to voice the popular wish. Many of our legislators to-day speak and write as though they were utterly ignorant of the existence of the

Digitized by Google

provision under which the Government, on the appraisement of five competent persons, can buy any telegraph system it may hanker after, if Congress will but vote the money, and if its owners are operating within the Act. That virtually means every telegraph company here, as no fewer than 101 have accepted the conditions in the 27 years since 1866. On their side, the companies attempted, while the Bill was under discussion, to obtain advantageous concessions, and at first glance it might seem that they secured some very valuable privileges; but as time has gone by the gains have faded from tangibility. The right to acquire public lands now means nothing. The right to run wires along post roads is a mockery. Every city in the Union, well-nigh, has a department organised expressly to keep poles and wires off the post roads, and drive them into subways; and more than one mettled Mayor, with a whetted axe, has himself been ready to lead on the forces of destruction. Moreover, the Government has priority, and some of its officials, ambitious of organising and directing a national telegraph service, have, I am sorry to say, made the most of such a provision, and of the power to fine for refusal to transmit, thus rendering the lives of the telegraph presidents anything but happy ones. Section 5,266 I venture to quote as bearing on this point:—

"Telegrams between the several departments of the Government and their officers and agents, in their transmission over the lines of any telegraph company to which has been given the right of way, timber or station lands from the public domain, shall have priority over all other business at such rates as the Postmaster-General shall annually fix; and no part of any appropriation for the several departments of the Government shall be paid to any company which neglects or refuses to transmit such telegrams in accordance with the provision of this section."

At one time this paragraph caught the fancy of such officials as I have alluded to as an admirable implement for baiting and goading the telegraph companies; but the sport lost its edge after a while, and was not revived until a few years ago, when resort was had to a scale of starvation rates, fixed by a Postmaster-General whose enemies allege that he was animated by motives of personal or political resentment.

These rates have, of course, varied a great deal. In 1845, after our Government had spent $30,000 on Morse's experimental line, the Postmaster-General fixed a common rate of one cent. for four characters. Congress then refused to buy the Morse patents for $100,000, and they fell back into private hands, the Postmaster-General reporting that "the operation of the telegraph between Washington and Baltimore had not satisfied him that under any rate of postage that could be adopted, its revenues could be made equal to its expenditures." This was hardly the public view of the situation when the great consolidations of 1866 took place, with their rapid doubling up of stock values, and hence, as I have hinted, came the Compromise Act, whose object, among others, was to secure cheap telegraphy for the Government should rates advance, as they have occasionally done under those conditions. That Act has certainly accomplished such a purpose very thoroughly. One considerable element of variation militating against the companies has been the increase in the length of their circuits. It might be said, without impropriety, that every time a company has extended its lines for commercial business it has rendered itself more vulnerable to possible Governmental imposition. In 1866 the length of the ordinary circuit upon which the rates were based was, perhaps, 100 or 200 miles. Now it is quietly assumed by the Government that the basic unit for tolls must be a circuit of not less than 1,000 miles. Since the pacification of the Southern States, our country has grown with wonderful leaps and bounds. Every year has witnessed the penetration by the telegraph lines of distant territory from which profit can only be expected in the future; yet the Government reaps immediate benefit. I will cite here the actual phraseology of the recent order from Postmaster-General Bissell, establishing rates for the current year 1893-94:—

"For day messages containing not more than twenty (20) words, exclusive of place from and date, twenty (20) cents, not exceeding one thousand (1,000) miles, and one cent for each additional word. One quarter of this rate to be added for each five hundred (500) miles, or fraction thereof, but no rate on a message of twenty (20) words to be more than forty (40) cents, nor on an additional word more than two (2) cents. The rate between all points in any State, territory, or the district of Columbia shall be twenty (20) cents for twenty (20) words, and one cent for each additional word.

"In cases where the price of a message, determined as herein provided, shall include a fraction of a cent, such fraction, if less than one-half, is to be disregarded; if one-half or more it is to be counted as one cent.

"For night messages not exceeding twenty (20) words, exclusive of place from and date, fifteen (15) cents for any distance within two thousand (2,000) miles, and for greater distances twenty-five (25) cents; in each case one cent for each additional word.

"Instead of computing the actual distances of transmission, the distance for payment shall in all cases be taken absolutely to be the number of miles between the capital of the State or Territory, or from the City of Washington, if from within the district of Columbia, from within which (whatever the place) the message is sent, and the capital of the State or Territory, or the City of Washington, if within the District of Columbia, within which (whatever the place) the message is received, as shown in the accompanying table, *wherein such distances are given as computed upon the shortest practicable route between such capitals*, and which is to be taken as part of this order.

"But it is provided that if on July 1, 1893, or at any time during the ensuing year, any such Company shall charge the public for a message of 10 words or less, exclusive of the date, address, and signature, a less rate than is herein fixed for 20 words, exclusive of place from and date, the rates here prescribed shall, as to such Company, thenceforth during the year be reduced to the rates so charged to the public."

In comparison with these rates I may state that under the present Western Union schedule the public pays for an ordinary 10-word day message, sent a distance of about 1,000 miles, 40 to 50 cents. A message to Chicago from New York—nearly 1,000 miles—costs 40 cents, but one to any other part of Illinois costs a private individual or a company 50 cents. It is provided in the Government schedule that no rate on a 20-word message shall exceed 40 cents, nor on an additional word more than 2 cents; but the ordinary rate to California—say 3,000 miles—for a 10-word message from New York is $1, and the rate per extra word is 7 cents. As an offset, making to the advantage of the Company, address and signature are counted in, but even then the reduction is a most substantial one. The cases I have cited above will serve to show how the system works.

The companies affected have, I may say, made no complaint against these rates, but those fixed by Mr. Bissell's predecessor were the subject of a bitter fight, still echoing in the Courts. Mr. Wanamaker, in 1889, made the Government rate 10 cents for 10 words, and ½ cent for each additional word, after trying to enforce a rate far lower than that. The Western Union Company objected strenuously, and refused to accept such terms, as being obviously far below actual cost. The average cost to the Company of a message is over 20 cents. It insisted that the Government had no right, and could create none, under the Constitution, by which it could make anybody sell it an article for less than the cost of production. At last the Company took its 10 cent allowance under protest, and its case, dating back to 1889, is now, I believe, awaiting adjudication in the Court of Claims at Washington.

One might imagine that with so much fuss and pother, the telegraph business from the Government would be enormous. But it is not, after every item has been counted in. My impression is that the Western Union Telegraph Company has several customers whose business exceeds that of the Government. It should be understood that the Government and the departments have some wires of their own, but these are of limited length and usefulness, and the bulk of the business must pass over private lines, just as the bulk of the mails passes over private railways. Army officers are under orders to make no use of the telegraph unless it is a case of dire necessity; but many of the civil branches are very free in their use of the wires, and would be more so but for the fact that appropriations are pretty closely watched.

The talk that was so abundant two or three years ago as to the Government acquisition of the telegraphs, or the establishment of a national competing system, is but faintly heard. The huge credit balance in the United States Treasury has dwindled away under the drain of the Pension List and the decline of trade, and now that we are discussing the issuance of bonds to meet ordinary expenditures, Government telegraphs have ceased to be a burning question. But the Act of 1866 is in vigorous operation; to its conditions every company in the field bows, and it has within its clauses all the potentiality necessary to convert our private lines into a system in every wise analogous to that which responds to the guiding hand of Mr. Arnold Morley.

CENTRAL STATIONS AND NEW TRANSFORMERS.*

BY G. CLAUDE.

The important improvements that have been made in the construction of transformers within the last three years is well recognised, and they have been brought out in a striking manner by Dr. Fleming, in his now classical Paper. From being a mediocre, and under certain conditions of working a detestable piece of apparatus, the transformer has passed at a bound to the front rank, and is now one of the most perfect instruments that the electrical industry has at its disposal. Formerly an important, and for a short time a preponderating, feature was the quantity of electrical energy transformed into heat. In modern transformers the heating is not so great as that of the best dynamos, and this has been attained without the sacrifice of any other valuable qualities, such as compactness, ability to run without supervision, and almost perfect self-regulation, which, in spite of all its other defects, soon marked out the transformer as a remarkable apparatus. No doubt, the alternate-current transformer, on which at an early date so many hopes were legitimately founded, although at that time nothing foreshadowed such rapid improvement, will benefit much from the progress that has been made. But now that the period of transition may be considered as ended, and transformer construction has arrived at such a pitch that it is not probable it will ever be appreciably improved, it is time to inquire whether all the results one might reasonably anticipate have followed. One would have supposed indeed that as soon as the results obtained had been corroborated the first care of those concerned would have been to replace their ancient old-fashioned apparatus by something up to date ; one would have thought that the almost complete suppression of the large amount

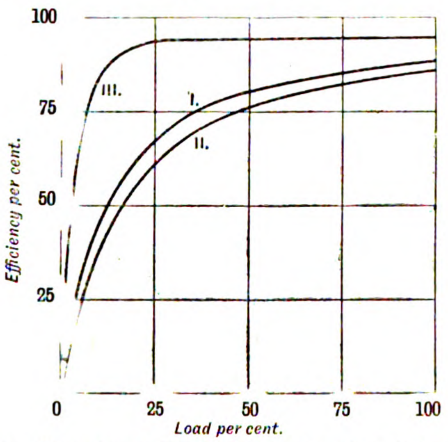

Fig. 1.—Transformer Efficiency as a Function of the Load.

of coal consumed by old transformers, in order to enable them to play the at once useless and expensive part of a stove, would in default of any other reason have been by itself enough to overcome all hesitation. It has not, however, been the case, and with the exception of quite recent installations the evolution of the transformer has not as yet received the *imprimatur* of practice. In France, amongst the numerous stations laid down previous to 1890 or 1889, the plant of which could not consequently profit by modern improvements, we can at the most only cite the Havre station, and perhaps one or two others, as having made the necessary alterations to their plant. This indifference of alternate-current stations to a question which is of such direct interest to them is astonishing enough to make one look for the cause of it in a lack of appreciation of the advantages which result to a station in getting rid of its old plant. It may not therefore be superfluous, I am inclined to think, to call attention to this point, and now I propose to do so.

To avoid generalities, I will devote my attention to the case of the old French stations, in most of which the consumers are supplied by old Ferranti transformers, which ought to be replaced by those of a more recent type. But first let it be remarked that all the transformers at present on the market being about as good one as the other, the conclusions arrived at can be applied indifferently to any pattern, although I have been obliged, in order to make my calculations, to base them on the experimental results of a certain particular type. Further, without attaching any particular importance to the choice, let me take as the typical transformer one of the Labour type, of which a description has been given already (*L'Industrie Électrique*, April 25, 1893). Let us assume, moreover, that the transformers in use are reduced to one common type of 7·5 kilowatts. By doing so we make an hypothesis favourable to the old plant, inasmuch as the transformers are nearly all of a smaller output, and that the efficiency of the old patterns decreases very rapidly with their nominal output, as can be seen by an inspection of curves I. and II. (Fig. 1), which relate to some old Ferranti transformers of 5·75 and 7·5 kilowatts. I now propose to determine the annual saving of energy consequent on the substitution of a Labour transformer of 7,500 watts (Curve III., Fig. 1), for a Ferranti transformer of the same power. The economy at different loads may be found by a comparison of the efficiency curves, if one has a knowledge of the power lost on open circuit. The open-circuit loss in the 7·5 kilowatt Ferranti transformer attains the enormous figure of 700 watts—that is to say, 9 per cent. of the full load, whilst the power lost in the Labour is only 140 watts, or barely 2 per cent. The following table gives as a function of the load the excess of power lost in the Ferranti transformer, compared with that lost in a Labour transformer of the same power :—

Load per cent.	Excess of power wasted, in watts.
0·0	560
2·5	640
5·0	630
10·0	610
20·0	600
50·0	570
100·0	570

Taking into account the long period of open-circuit working, and remembering that transformers practically hardly ever work at more than from 2 to 10 per cent. of full load, but work for the greater part of the time either on open circuit or only at a fraction of the maximum load, we arrive at this interesting conclusion : that whatever be the time of year or day, the economy realised by merely replacing a transformer is near yconstant, and amounts, at least, to 570 watts. In consequence, ccording as the current is cut off during the day—that is to say, during about 12 hours, or the transformers are in circuit during the whole 24 hours, the daily economy in energy will amount to 7·0 or 13·5 kilowatt hours, aggregating in one year to 2,500 or 5,000 kilowatt hours for each transformer.

In spite of the importance of this result the preceding considerations are nevertheless insufficient for the proper appreciation of the economy realised. In almost all the stations, indeed, the nominal output of each transformer is much greater than the effective demand of the circuit which it has to supply ; this was done either in anticipation of a further increase of the demand, or because at the time these installations were laid down a sufficiently exact estimate was not made of the importance of getting as near as possible to working on full load. It is certain that with the conditions of heating inherent in the apparatus then in use it would have been impossible to follow with impunity the excellent method which has since been put into practice, notably in the Champs Élysées district. This system is based on the fact of the short duration of the full load and currents, including the transformers' work at the moment of maximum demand above their nominal output. It is certain that in numbers of stations the transformers work at the time of full load at 50 per cent. of their nominal output. Without speaking of the first cost of the installation, which is very considerable when it is so arranged, I will only point out this result, namely, that the loss on open circuit is no longer the 9 per cent. to which allusion was made just now, but in reality 18 per cent. of the full load. We see, then, that it would be a great mistake to admit the specious reasoning that a bad efficiency matters little at low load, since at that moment the output of the transformer is very small. In fact, I have shown that this loss is, with old plant on low load, far from being as small as we were led to suppose. Moreover, the time factor comes in to give the conditions of working on low load a preponderating influence. The consequences of holding such erroneous views can be better appreciated after an inspection of the curves (Figs. 2 and 3), which relate to normal working conditions, Fig. 2 corresponding to an average summer load, and Fig. 3 to an average winter load, the transformers being in circuit during the whole of the 24 hours. The curves in Figs. 4 and 5 show the alteration which would result from the installation of modern transformers, in which the open-circuit loss can be reduced to 4 or 5 per cent., and even less, if we follow the Champs Élysées plan. From this we see the energy saved will amount to from 20 to 50 per cent. of the output, according as it is winter or summer.

The economy which has just been discussed may be looked at from two points of view, namely, as diminishing the cost of production, and as increasing the useful output. As to the first, it is obvious that the daily economy of from 20 to 50 per cent. of the output of a station does not show itself in a proportionate diminution of the cost of production, the only consequence is, in fact, to lighten the load on the engines, a relatively large diminution when the transformers are on open circuit. If it be impossible to take

* From *L'Industrie Électrique*.

Digitized by Google

advantage o' his . sened load by running a smaller engine* we can, nevertheless, diminish the steam, and, therefore, the coal consumption. On the other hand, at the time of maximum load, the available effective output of the station is, by the mere fact of having

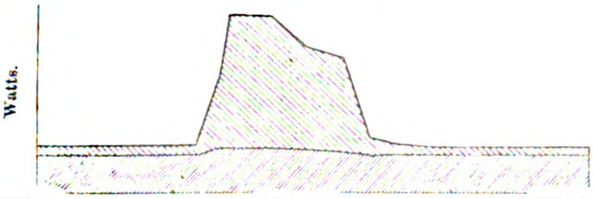

FIG. 2.—Summer.

substituted new transformers, increased by 12 to 14 per cent., which allows of a corresponding increase in the number of consumers without any increase of plant. These two advantages are sufficiently important to enable us, where the conditions are worst, to make

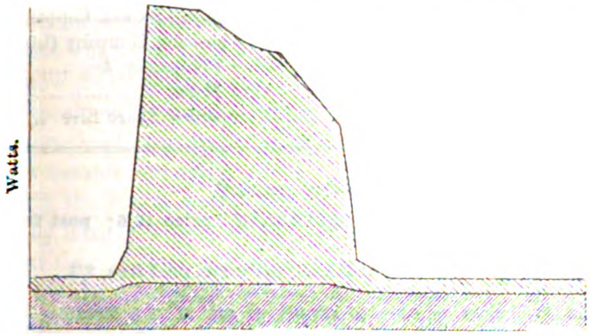

FIG. 3.—Winter.

good in a very short time the outlay on new transformers, from which indeed must be deducted the value of the old material. If it be possible, as it is in some stations, to absorb all the power thus rendered available, either in producing a continuous current

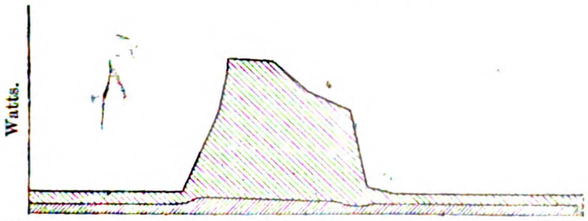

FIG. 4.—Summer.

and charging accumulators with it, or in any other way, the reform will prove still more beneficial. In that case the energy saved will no longer be, as we have assumed, merely deducted from the output, but will become useful, and in that case it will be necessary

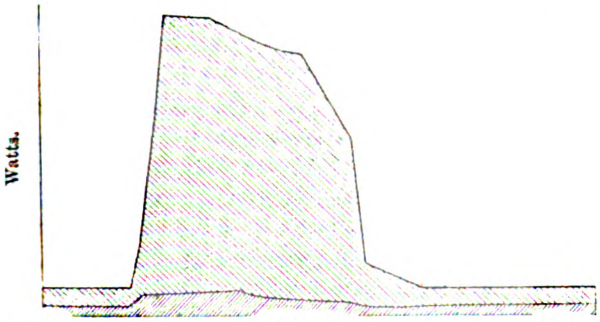

FIG. 5.—Winter.

to credit each kilowatt-hour saved with its cost of production. In such circumstances the first cost could be covered in a few months.

* It is well known, the advocates of accumulators in central stations having called attention to the fact pretty often, that the labour, oil, and maintenance bills remain constant under these conditions, whilst the efficiency is lowered.

THE RESISTANCE AND THERMO-ELECTRIC POWER OF HYDROGENATED PALLADIUM.*

BY G. BRUCCHIETTI.

Palladium in the form of thin plates deposited by electrolysis occludes the greatest quantity of hydrogen, the quantity reaching 985 volumes when the lamellæ are heated in the gas to 100deg. and then cooled. For determining the resistance and the thermo-electric force of a pile consisting of a palladium wire 10cm. long and 1mm. in diameter and pure nickel wire, the palladium wire was placed at the cathode of a voltameter, arranged in series with another water voltameter to determine the amount of hydrogen absorbed. Special precautions were adopted to ensure a uniform absorption of hydrogen, and the absorption was carried as far as 936 volumes at the ordinary temperature and pressure.

The palladium, when hydrogenated, assumes a peculiar brown tint and loses its flexibility. The hydrogen may be withdrawn by heating the wire to a bright red in a gas flame for a few minutes. Repeated charges and discharges make the metal brittle, most of the specimens breaking down at the fifth discharge.

The palladium and nickel for the thermocouple were very pure, and were obtained from the Trommsdorff establishment. They were soldered together by means of silver, and the currents were compared with those from a copper-iron couple.

The results show that in a couple composed of pure and hydrogenated palladium respectively the thermo-electric current will pass from the latter to the former across the hot junction.

The resistance increases with the charge of hydrogen, and a saturated wire has a specific resistance 1·553 times as great as the pure wire. The thermo-electric power of a palladium-nickel couple also increases with the number of volumes of hydrogen absorbed, and the saturated couple shows a thermo-electric force 1·66 times that of the pure palladium-nickel couple. The resistance and the thermo-electric power both increase in a linear ratio.

After repeated charges and discharges of hydrogen, the difference between the behaviour of the palladium in the two states is less marked, and it is probable that after a large number of such operations a state would be reached in which *the presence or absence of hydrogen would make no difference.*

* *L'Elettricista*, November, 1893.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, November 24th.

PHYSICAL SOCIETY.

5 p.m. (1) "The Magnetic Shielding of Concentric Spherical Shells," by Prof. A. W. Rücker, M.A., F.R.S., President. (2) "The Action of Electromagnetic Radiation on Films containing Metallic Powders," by Prof. G. M. Minchin, M.A.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Concert at St. James's Hall Restaurant (Ladies' Night).

TUESDAY, November 28th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Discussion on:—"Impounding Reservoirs in India, and the Design of Masonry Dams," by Messrs. Clerke, Sadasewjee, Col. Jacob, and Prof. Kreuter.

WEDNESDAY, November 29th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "The Regulation of Street Advertising," by Richardson Evans.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Magnetic Induction at Varying Pressure and Temperature. M. Curie has recently studied the relation between the magnetic properties of a gas and the conditions of temperature. He finds that the permeability of oxygen is constant between inductions of from 200 to 1,350 C.G.S. units, and pressures of from 5 to 20 atmospheres, when the temperature of the gas remains unchanged; also that the permeability varies inversely as the temperature (presumably in absolute degrees) between the limits of 20°C. and 450°C. on the ordinary scale. A further development of these relations would throw some light on the relationship of magnetic induction to the elasticity and density of gases.

The Electrician.

(The Oldest Electrical Journal.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :
1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

TELEGRAPHS IN THE UNITED STATES.

According to intelligence just received from New York, another attempt is being made in the United States Senate to induce the Government to undertake telegraph business, this time not by acquiring existing systems, but by competing with them. The idea is not, to our thinking, a very promising one, having all the drawbacks of the British Government telephone scheme without any of its excuses. As a measure of self-preservation the erection of trunk telephone lines by the Government instead of by private enterprise is not without justification; but for a Government to erect wires, either telephonic or telegraphic, and work them in opposition to a fully-established system belonging to a commercial company, is neither politic nor fair. If the competition is confined to a limited number of lines, as proposed by Senator BUTLER—that is to say, in the areas that are most remunerative—the greatest injury would be inflicted on the telegraph companies, but without any commensurate benefit to the public at large. If, on the other hand, the conflict were conducted seriously, and with the intention of gradually but effectually superseding all the working companies, the process would involve a huge waste of public money, larger by far than might be needed to purchase outright the whole concerns.

It has long been a matter of wonderment in this country that the United States has not followed the example of European Governments in this respect. We have seen it urged on behalf of American private enterprise that to hand it over to the State would increase to that extent the number of place-hunters. But in a country where "spoils to the victors" is a recognised political axiom this objection would seem to have little weight. A more cogent reason, perhaps, is one let fall incidentally by Mr. T. C. MARTIN in his article on the United States telegraphs, which appears in our columns this week. An impression has prevailed everywhere outside the States that it possesses a reserve of wealth somewhere, gathered

Digitized by Google

up from surplus taxation, arbitration awards, and similar windfalls, of embarrassing dimensions, and greater than it knows what to do with. Why not spend it on purchase of the telegraphs? But Mr. MARTIN, who is on the spot, informs us that the much-talked-of credit balance in the United States Treasury has long been a vanishing quantity and is now non-existent. Bad trade is accountable for this partly, but pensioners mostly. In America, State pensioners who do not live for ever continue to receive their warrants in the next world; and even the German Emperor's war hoard could not hold out against a drain such as that.

The excuse therefore for inaction, or for action of the feeble sort recommended by Mr. BUTLER, is, that the United States is too poor to buy up the telegraphs and take over their management. We scarcely credit it, though we admit that the undertaking, compared with our own of twenty-three years back, is of unwieldy proportions. Still the United States may be credited with knowing its own affairs best; and we agree with Mr. MARTIN that the talk about State purchase of the telegraphs is now but faintly heard so far as America is concerned. Unconsciously, perhaps, Mr. MARTIN's interesting article supplies us with the most potent reason of all for the present system remaining undisturbed. The initiative must always rest with the Government, and so long as the Government profits by letting matters alone, we shall not expect it to move. And that it does profit, Mr. MARTIN demonstrates in a way that will be a surprise to most of our readers. The hitherto mysterious fact that, while claiming no ownership or control of the telegraph lines, the American Government determines the rates to be charged for its own telegrams, receives a full explanation at Mr. MARTIN's hands. We are reminded of the relations subsisting here between the railway companies and the Post Office—concessions gradually diminishing on one side, but growing rapidly and to enormous dimensions on the other. For conceding rights-of-way, timber and station lands to the American telegraph companies—rights which have proved inoperative against the attacks of municipalities—the Government exacted the power to fix its own rates; a power exercised to this day, and on the same basis as when the lines did not extend a tenth of the distances they cover now. These governmental rates are subject to revision every year, on much the same principle as Mr. BENJAMIN PICKARD, M.P. for British miners, particularly favours, namely, that every advantage is taken of prosperous times, but nothing yielded to the unprosperous.

Nobody can read the conditions under which, in these respects, the American telegraph companies carry on business without feeling that they are badly handicapped by the States Government. But our sympathy is not for them alone or chiefly. That they submit to it is only to be explained by the facility they enjoy of making the public pay. We in this country can understand the Government stipulating for workmen's trains in consideration of concessions to railway undertakers. That is Democratic Socialism. But things are different in the great Republic, where the State, so to speak, takes the workmen's ticket and lets him pay the difference. Of course, the whole business is a costly extravagance looked at from a broad and national point of view; but until the American people wake up to that fact it need not surprise us much that the Government remain satisfied with an arrangement under which its telegrams are accepted at greatly reduced rates. That arrangement would be certainly broken up if Senator BUTLER's project were set on foot, for even the long-suffering telegraph corporations would rise in revolt against a competitor who underpaid them in one direction and undersold them in another.

COMPENSATION FOR HYSTERESIS.

BY H. ABDANK-ABAKANOWICZ.

My attention was directed to an article on the same subject by Mr. E. B. Vignoles, in which this gentleman indicates a method applied by Mr. Evershed and himself for diminishing the effects of hysteresis in measuring instruments containing iron.

Mr. Vignoles, after describing Mr. Evershed's method, alludes to my method, and in view of the closing paragraph of his article, in which occurs the following sentence:—"It seems desirable, however, that, in view of the publication of M. Abdank-Abakanowicz, the results of our earlier work should be put on record in these pages," I feel called upon to draw a short comparison between our methods, in order to avoid possible confusion in the minds of the readers of *The Electrician* as to the similarity or difference in the two methods.

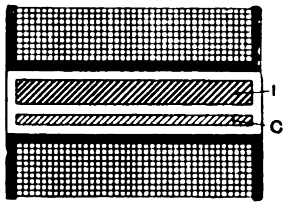

FIG. 1.

Before going any further, I wish to make the statement that neither I nor my distinguished collaborator (Mr. Meylan), who did all the experimental work on this subject, have made any publications concerning it, everything that has been published emanating probably from the records of the different Patent Offices, which are not precisely the sources for purely scientific information. It is, therefore, probably too early to try, from what has been published on the subject so far, to establish a satisfactory comparison between the two methods. However, to show that there is considerable difference between the two, it may be interesting to the readers of *The Electrician* to see the following two examples, one representing Mr. Evershed's method, and the other my own.

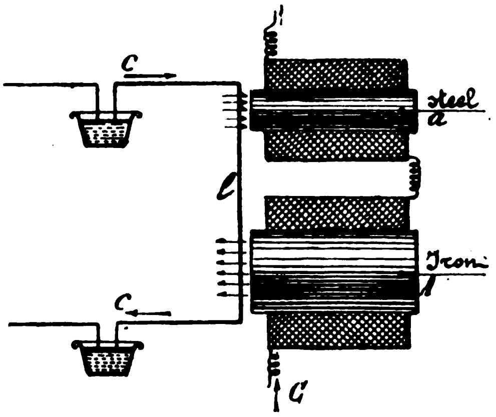

FIG. 2.

Method of Mr. Evershed.—The device of Mr. Evershed is described by Mr. Vignoles as follows:—

"The simplest form of the Evershed method is illustrated by the adjoined sketch, which represents a section of a coil magnetising the iron cores I and C. Suppose the current tends to make the left side north, and suppose that C is made of hard steel, and has, therefore, a much greater coercive force than the soft iron I. When the current is cut off the core C remains more intensely magnetised than I, which is thus demagnetised, and may be reversed. By suitably proportioning the parts the effect outside the core may be entirely obliterated."

This method of diminishing the effect of residual magnetism in special cases is so simple that it needs no further explanation.

Method of Abdank-Abakanowicz.—Let us consider the simplest form of a device consisting of a single wire, *l* (Fig. 2), on which

Digitized by Google

are acting the lines of forces of two electro-magnets A and *a*, the former with an iron and the latter with a steel core. The electro-magnet A, of larger section, acts in one direction and the electro-magnet *a* in another, as indicated by arrows. We will suppose that the same current C is flowing through A and *a*. The force exercised by A on *l* will (the current flowing through *l* being invariable) be represented in function of the current in the electro-magnets by a curve which is simply the curve of magnetisation of the core A, and which affects the well-known

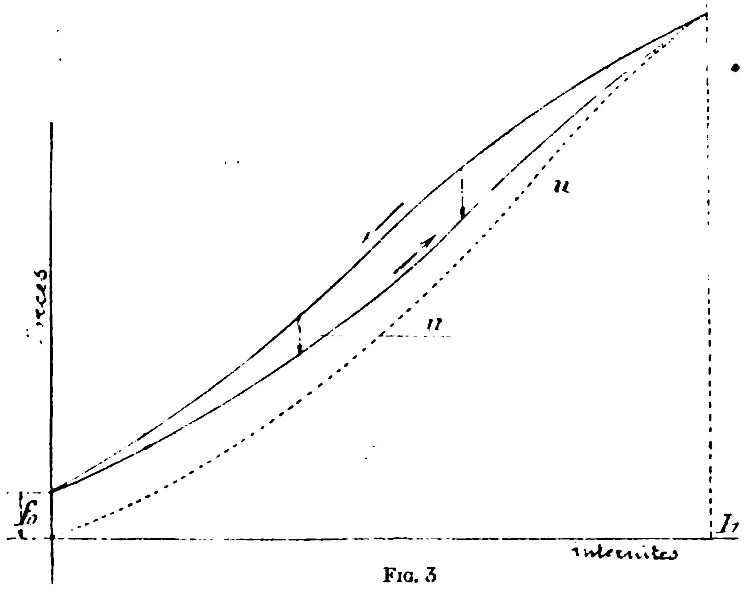

Fig. 3

form of Ewing's cycles (Fig. 3). We admit here that we are starting from zero, and that we follow the cycle in the positive part of the field. The force exercised by the smaller electro-magnet, *a*, is represented by a nearly similar function (the curve is not indicated on Fig. 3), but in which the ordinates of the loop *u u* have a greater relative value. It is easy to understand that by an appropriate choice of the magnetic conditions of the two systems A and *a*, we can arrive at the following results.

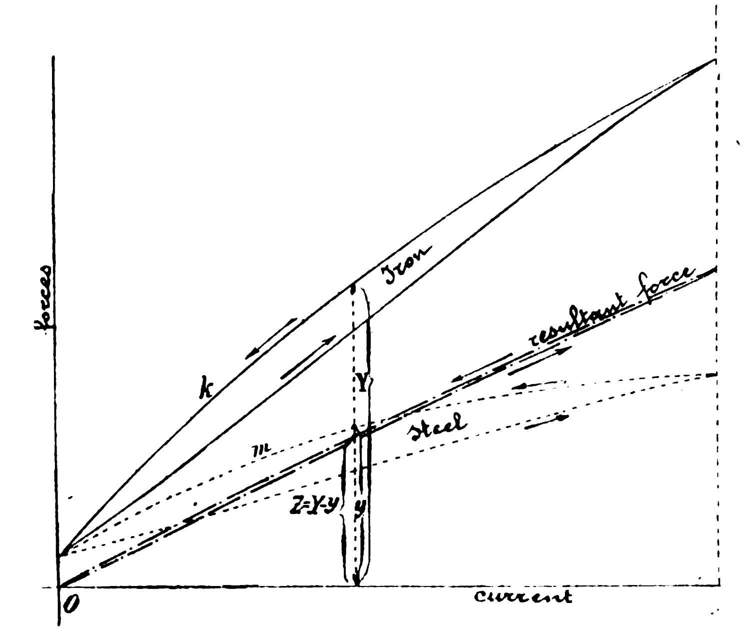

Fig. 4.

1. The remanent magnetism f_0 of the iron is equal to the remanent magnetism of the steel, for the different values of maximum current C obtained in each experiment, and, as the resultant force is the algebraical sum of the actions of A and *a*, and as they are equal, and of opposite sense, the remanent magnetism is zero.

2. The ordinates *u u* of the two loops can be made nearly equal for the correspondent values of the current and for different values of the maximum current. In such conditions the resultant force on the wire, *l*, which is equal to the *difference* of the two elementary forces, will be a definite function of the current C, and will not therefore present the effects of hysteresis, *i.e.*, there will be approximately no loop.

3. Furthermore, the curve of resultant forces having ordinates (Fig. 4) equal to the difference of the ordinates of the two curves *k* and *m*, and these having convexities and concavities of similar character, this resultant curve will approach to a straight line.

Fig. 4 shows how the correction is effected for cyclic variations of current from zero to the maximum value C. Several instruments that we have constructed have given proof that by appropriate choice of conditions it is possible to obtain deviations proportional to the current within very large limits. The principal difficulty consists in maintaining equilibrium when the current reaches a value very much in excess of the given limit. In a very short time we will publish the results of our experimental work on this subject.

TESTS OF GAS BURNERS.

While no exact comparison between the cost of electric ligh by glow lamps and by gas burners is possible, because of th variety of the one and the gradual deterioration of the other, som better estimates may be made than the wild and thoughtles statements of enthusiastic electricians, or the deliberately mis leading figures of many gas engineers. The electricians to often consider little else than volts and amperes, and concoc imaginary coal bills and wages accounts. Gas engineers, o the other hand, almost invariably take a standard Argan burner as a base for their comparisons. Tests of ordinar burners are rarely seen. Gas engineers are probably aware the performance of ordinary burners, but the figures are nev alluded to. One of the only occasions on which tests of comm burners have been published was a report by Dr. J. Hopkins on a system of enriching gas by hydro-carbon vapour som four or five years ago. The peculiarity of this system was th the worse the burner the better was the effect; it may ha failed because no burner was bad enough to do justice to it.

We cannot, of course, afford to devote much of our space the discussion of gas lighting; but in view of the importan of making a fair comparison between lighting by gas and l electricity, we offer our readers an abstract of a very caref and complete report on "The Photometry of Gas Burner made by three students at the Central Institution of the Ci and Guilds of London, under Prof. Ayrton. The observe were Mr. H. C. Haycraft, Mr. A. T. Weightman, and Mr. C. Gawthorp.

The apparatus used was the following:—A Bunsen pho meter, with grease-spot and mirrors; a photometric be about 200cm. long, of which a length of 150cm. was usual employed; a Sugg meter, placed between a regulating tap a the burner under test, giving cubic feet per hour by observ tion during one minute, *i.e.*, reading sixtieths of a cubic foo a pressure gauge, placed between meter and burner; a Met ven two candle standard, used without pentane; and a reflect used in obtaining spherical candle-powers, 5in. in diamet mounted on an axis at 45deg. to its plane.

The report contains an account of the calibration of t meter by displacement of water. The first result showed th it read 0·3 per cent. too high. In other tests in which the ta meter, and collector were differently placed, the results we 1 per cent. too low and 1 per cent. too high, showing th within the limits of experimental error the meter was corre Experiments were made to find the error due to variation the water level from the mark on the meter. Other necessa corrections seem to have been made, with two rather importa exceptions. The barometric pressure was not recorded, and is remarked, in the report, that the mass of gas correspondi to a given reading of the meter may vary within about 10 p cent., the result is in favour of the consumer in fine weathe The other omission is a correction for temperature. It is we known that the candle-power of gas is considerably affected b changes of temperature of the surrounding air,

Digitized by Google

For determining the spherical candle-powers, a 5in. circular [mi]rror, A, was mounted on a wooden frame attached to a brass [tu]be at an angle of 45deg., Fig. 1. This tube rotates in a [sp]lit tube mounted horizontally, and carries at its end a disk, B, [div]ided into 5deg. divisions. The distance from the centre of [th]e mirror to the vertical axis was eight centimetres. The [co]efficient of absorption of the mirror was determined by the

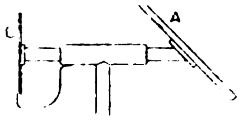

Fig. 1.

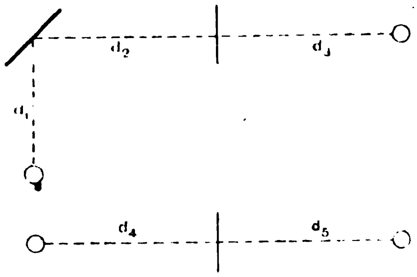
[fol]lowing method. A No. 6 Bray's "special" burner was first [co]mpared with the standard in the usual manner, and then [m]oved out at right angles to the bench, its place being taken [b]y the mirror, the ratio of the candle-power in the first to that [in] the second position is termed the absorption coefficient.



[Fi]g. 2.—Measurement of Absorption of Mirror :—d_1, distance from [bu]rner to mirror ; d_2, distance from mirror to photometer ; d_3, distance [fro]m photometer to standard ; d_4, distance from burner to photometer, [witho]ut mirror ; d_5, distance from photometer to standard.

The following are a few of the observations :—

d_1	d_2	d_3	d_4	d_5	Apparent C.P.	Real C.P.	Absorption coefficient.
[illegible]5	94·4	47·6	111·8	38·2	14·62	17·2	1·18
[illegible]5	79·7	62·3	99·6	50·4	6·26	7·8	1·25
[illegible]	97·7	44·5	113·5	36·5	16·45	19·3	1·173
[illegible]	66·3	75·7	87·8	62·2	3·23	3·99	1·24

[Th]e mean of a number of determinations was 1·22.

The Methven Standard was compared with a Harcourt [Pen]tane Standard, and was found to agree very closely with it. [The] height of the flame of the Pentane burner was adjusted [by] the occasional application of a spirit flame, since the perma[nen]t height of the flame lags considerably behind an adjustment [of] the wick.

Tests of Gas Burners.

The gas burners tested consisted of Sugg's, Bray's, Albo [Car]bon, and Wenham. From one-third to one-half of the [obse]rvations have been omitted in the following abstract :—

I.—*Governed Burners.*

From the above results, and the curves plotted from them, it is deduced in the Report that—

(1) Governed burners, though their maximum efficiency is no greater than that of ungoverned ones, have the advantage of a more uniform efficiency, especially seen where high pressures are used. The candle-power also remains fairly uniform for considerable changes in the pressure.

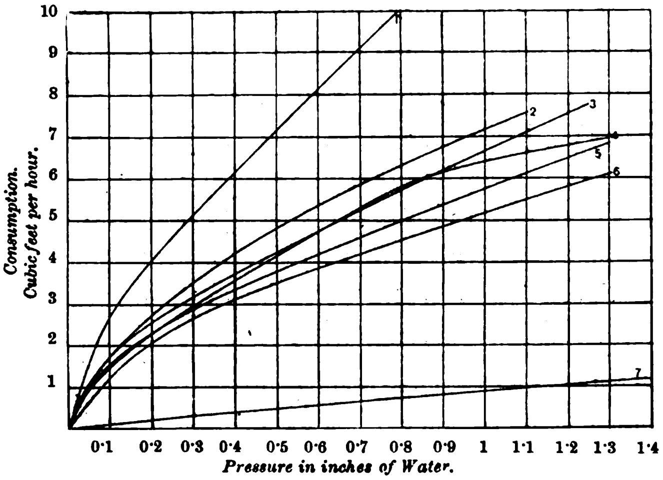

Fig. 3.—Consumption and Pressure.

1. Sugg's Table Top No. 5, Ungoverned.

4. Bray's No. 6, Union Jet, Special.
5. Bray's No. 6, Enamel Regulator, Union Jet.
6. Bray's No. 4, Special Union Jet.
7. Bray's No. 4, Enamel Regulator Union Jet.
8. Sugg's No. 1, Table Top, Ungoverned.

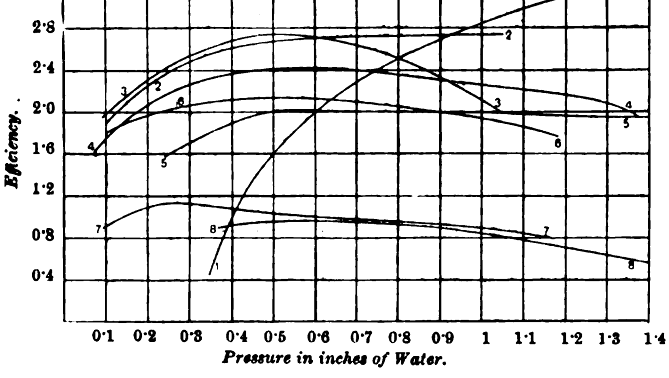

Fig. 5.—Efficiencies (candle-power / cubic feet per hour) and Pressure.

1. London Argand.
2. Sugg's No. 5, Table Top, Governed.
3. Ditto ditto Ungoverned.
4. Fray's No. 6, Union Jet, Special.
5. Bray's Burner for Street Lamps, with Governor.
6. Bray's Enamel Regulator, No. 6, Union Jet.
7. Bray's No. 2, Regulator, Union Jet.
8. Sugg's No. 1, Table Top, Ungoverned.

(2) Of the ungoverned burners Sugg's appear to be more efficient than Bray's. Sugg's No. 5 table-top ungoverned reaches an efficiency of 2·72, while Bray's No. 5's average 2·3 as maximum efficiency, and only one reaches 2·52.

(3) Throughout the above results we see that the efficiency (max.) of all burners increases with the size of the burner, *cœteris paribus*, and that even for low candle-powers it usually pays to use a large burner.

(4) As regards Bray's burners, his "Special" type has a somewhat higher efficiency than the ordinary enamel regulators, and the efficiency does not fall off so much at high pressures. Of the three types of flame—slit-union, batswing, and union-jet—the slit-union and batswing burners are considerably more efficient than the ordinary union-jet burner, the batswing being usually rather less efficient than the slit-union.

Burners for large candle-powers (Bray's and Wenham's).

1. Bray's "standard" burners for large candle-powers.—Two "standard" burners of 30 and 80-c.p. nominal were tested. The two candle power standard being unsuitable for this work an Argand burner was used whose candle-power was found before and after the experiments. It was not found to var appreciably whether the large burners were in use or not. Candle-power of Argand = 14·9. Dist nce from argand t burner to be tested 190cms.

30-c.p. "Standard—

Distance of photometer from Argand.	C.P.	Cub. ft. per hr.	Pressure.	Efficiency C.P./C.F.	Face or edge of flame.
70·5	43·0	17·85	1·5	2·41	Edge.
67·2	49·8	17·85	1·5	2·79	Face.
74·3	36·2	11·8	0·75	3·07	Face.
82·0	25·9	8·45	0·5	3·07	Face.

80-c.p. "Standard"—

Distance of photometer from Argand.	C.P.	Cub. ft. per hr.	Pressure.	Efficiency C.P./C.F.	Face or edge of flame.
57·3	80·0	23·2	1·3	3·45	Face.
64·2	57·3	23·2	1·3	2·47	Edge.
68·6	46·8	14·3	0·6	3·28	Face.
79·0	29·5	9·8	0·3	3·01	Face.

The above efficiencies are fairly high and fairly unifor It may be noticed that whereas the candle-power of ordina burners only varies about 5 to 10 per cent. between edge a full face, the variation with these large burners is great being nearly 30 per cent. in the case of the 80-c.p. burn These burners take too much gas to be run from an ordina tap; they were run from a half-inch pipe, and this only su plied just enough gas for the 80-c.p. burner.

(To be concluded.)

BOARD OF TRADE ELECTRIC TRAMWAY REGULATIONS (DRAFT).

The Electric Powers (Protective Clauses) Joint Committee this session reported that statutory powers for the use of e tricity by tramway and railway companies should be quali by regulations to be made by the Board of Trade for protection of the electric circuits of other parties, and pipes of gas and water companies, &c. The accompany draft regulations have consequently been prepared and mitted for the consideration of the Board of Trade :—

Draft.

Regulations made by the Board of Trade under the provisions of the Tramways Act, for regulating the employment of insulated returns, uninsulated metallic returns of low resistance; for preventing fusio injurious electrolytic action of or on gas or water pipes or other me pipes, structures, or substances; and for minimising as far as is reaso practicable injurious interference with the electric wires, lines, apparatus of parties other than the company, and the currents the whether such lines do or do not use the earth as a return.

Definitions.

In the following regulations—

The expression "energy" means electrical energy.

The expression "generator" means the dynamo or dynamos or o electrical apparatus used for the generation of energy.

Digitized by Google

The expression "motor" means any electric motor carried on a car and used for the conversion of energy.

The expression "pipe" means any gas or water pipe or other metallic pipe structure or substance.

The expression "wire" means any wire or apparatus used for telegraphic, telephonic, electrical signalling, or other similar purposes.

The expression "current" means an electric current exceeding one thousandth part of one ampere.

The expression "the company" has the same meaning as in the Tramways Act.

Regulations.

1. Any dynamo used as a generator shall be of such pattern and construction as to be capable of producing a steady continuous current.*

2. One of the two conductors used for transmitting energy from the generator to the motors shall be in every case insulated throughout its length, and is hereinafter referred to as the "line"; the other may be insulated throughout, or may be uninsulated in such parts and to such extent as is provided in the following regulations, and is hereinafter referred to as the "return."

3. Where any rails on which cars run or any conductors laid between such rails form any part of a return, such part may be uninsulated. All other returns or parts of a return shall be insulated.

4. When any uninsulated conductor laid between the rails forms any part of a return it shall be electrically connected to the rails at distances apart not exceeding 100ft. by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or by other means of equal conductivity.

5. When any part of a return is uninsulated it shall be connected with the negative terminal of the generator, and in such case the negative terminal of the generator shall also be directly connected, through the current indicator hereinafter mentioned, to two separate earth connections which shall be placed not less than 20 yards apart.

Provided that in place of such two earth connections the company may make one connection to a main for water supply of not less than 4in. internal diameter, with the consent of the owner thereof.

Such earth connections shall be constructed, laid, and maintained, so as to secure contact with the general mass of earth, and so that an electromotive force, not exceeding four volts, shall suffice to produce a current of at least two amperes from one earth connection to the other through the earth, and a test shall be made at least once in every month to ascertain whether this requirement is complied with.

Where any portion of either earth connection is placed within 6ft. of any pipe, and the company are unable to obtain permission to metallically connect it with the earth connection, they shall provide, by means of a non-conducting screen, that no current can pass between the pipe and the earth connection, without traversing at least 6ft. of earth.

6. When the return is partly or entirely uninsulated the company shall in the construction and maintenance of the tramway (*a*) separate the uninsulated return from the general mass of earth, and from any pipe in the vicinity; (*b*) connect together the several lengths of the rails; (*c*) adopt means for reducing the difference produced by the current between the potential of the uninsulated return at any one point and the potential of the uninsulated return at any other point; and (*d*) maintain the efficiency of the earth connections specified in the preceding regulations, so as to fulfil the following conditions, viz.:—

(i.) That the current passing from the earth connections to the generator shall not at any time exceed 10 amperes.

(ii.) That if at any time and at any place a test be made by connecting a galvanometer or other current indicator to the uninsulated return and to any pipe in the vicinity, the direction of the current, if any, shall be from the return to the pipe and not *vice versâ*.

(iii.) That under the conditions specified in (ii.) it shall always be possible to reverse the direction of the current by interposing a battery of three Leclanché cells connected in series.

In order to provide a continuous indication that the condition (i) is complied with, the company shall place in a conspicuous position a suitable, properly connected, and correctly marked, current-indicator, and shall keep it connected during the whole time that the line is charged.

The owner of any pipe may require the company to permit him to ascertain by test that the conditions (ii.) and (iii.) are complied with as regards his pipe.

7. When the return is partly or entirely uninsulated its electrical resistance shall be tested by the company at least once in every three months. If at any such testing it appears that the resistance has increased by more than 15 per cent. above the value recorded at the time the tramway was opened, the company shall take immediate steps to reduce the resistance to the said recorded value.

8. Every electrical connection with any pipe shall be so arranged as to admit of easy inspection, and shall be tested by the company at least once in every three months.

9. Every line and every insulated return or part of a return shall be constructed in sections not exceeding one half of a mile in length, and means shall be provided for isolating each such section for purposes of testing.

10. The insulation of the line and of the return when insulated, and of all feeders and other conductors, shall be so maintained that the leakage current shall not exceed one-hundredth of an ampere per mile of tramway. The leakage current shall be ascertained daily before or after the hours of running when the line is fully charged. If at any time it should be found that the leakage current exceeds one-tenth of an ampere per mile of tramway, the running of the cars shall be stopped until the leak has been localised and removed.

11. The insulation resistance of all lines, insulated returns, feeders, or other conductors, laid below the surface of the ground, shall not be permitted to fall below the equivalent of 10 megohms for a length of one mile. A test of the insulation resistance of each part of the circuit shall be made at least once in each month.

12. Where in any case in any part of the tramway the line is erected overhead and the return is laid on or under the ground, and where any wires have been erected or laid before the construction of the tramway in the same or nearly the same direction as such part of the tramway, the company shall, if required so to do by the owners of such wires or any of them, permit such owners to insert and maintain in the company's line one or more induction coils or other apparatus for the purpose of preventing disturbance by electric induction.

13. Any insulated return shall be placed parallel to and at a distance not exceeding 3ft. from the line when the line and return are both erected overhead, or 13in. when they are both laid underground.

14. In the disposition connections and working of feeders the company shall avoid injurious interference with any existing wires.

15. The company shall so construct and maintain their system as to secure good contact between the motors and the line and return respectively, and they shall not allow sparking to occur at the rubbing or rolling contacts in any part.

16. In working the cars the current shall be varied as required by means of a rheostat containing at least 20 sections, or by some other equally efficient method of gradually varying resistance.

17. In the construction and use of their generator and motors the company shall take all reasonable precautions to prevent the occurence of undue sparking.

18. Where the line or return or both are laid in a conduit the following conditions shall be complied with in the construction and maintenance of such conduit:—

(*a*) The conduit shall be so constructed as to admit of easy inspection of, and access to, the conductors contained therein and of all insulators and supports.

(*b*) It shall be so constructed as to be readily cleared of accumulation of dust or other *débris*, and no such accumulation shall be permitted to remain.

(*c*) It shall be laid to such falls and so connected to sumps or other means of drainage as to automatically clear itself of water without danger of the water at any time reaching the level of the conductors.

(*d*) If the conduit is formed of metal, all separate lengths shall be so jointed as to secure metallic continuity for the passage of electric currents, and where the rails are used to form any part of the return they shall be electrically connected to the conduit by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or other means of equal conductivity, at distances apart not exceeding 100ft. Where the return is wholly insulated and contained within the conduit, the latter shall be connected to earth at the generating station through a high resistance galvanometer suitable for the indication of any contact or partial contact of either the line or the return with the conduit.

(*e*) If the conduit is formed of any non-metallic material not being of high insulating quality and impervious to moisture throughout, and is placed within 6ft. of any pipe, a non-conducting screen shall be interposed between the conduit and the pipe, of such material and dimensions as shall provide that no current can pass between them without traversing at least 6ft. of earth.

19. The company shall, so far as may be applicable to their system of working, keep records as specified below. These records shall, if and when required, be forwarded for the information of the Board of Trade.

Daily Records.

No. of cars running.
Maximum working current.
Maximum working pressure.
Maximum current from the earth connections (*vide* Regulation 6, i.).
Leakage current (*vide* Regulation 10).

Monthly Records.

Condition of earth connections (*vide* Regulation 5).
Insulation resistance of different conductors (*vide* Regulation 11).

Quarterly Records.

Resistance of return (*vide* Regulation 7).
Conductance of joints to pipes (*vide* Regulation 8).

Occasional Records.

Any tests made under provisions of Regulation 6 (ii. and iii.).
Localisation and removal of leakage, stating time occupied.
Particulars of any abnormal occurrence affecting the electric working of the tramway.

* The Board of Trade will be prepared to consider the issue of regulations for the use of alternating currents for electrical traction on application.

Science Scholarships.—The Coutts Trotter Studentship, of the annual value of £250, for the promotion of original research in Natural Science, more especially in Physiology and Experimental Physics, open to graduates of Trinity College, not being Fellows, of not more than seven years' standing from the time of commencing residence, has been awarded to Mr. Daniel Henry Moore, B.A., scholar of Trinity College. Mr. Moore obtained a first-class in the Natural Sciences Tripos, Part I., June, 1891, and a first-class for Physics in the Natural Sciences Tripos, Part II., June, 1893.

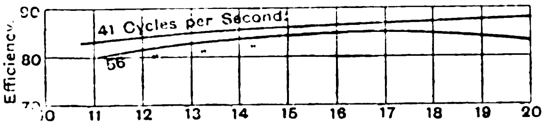
THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.*

BY PROF. GEORGE FORBES.

(Continued from page 72.)

But the most obvious advantage of low frequency is the improved efficiency of motors. I have arrived at this conclusion from my own observations, but I find it confirmed collaterally. With synchronising motors, of course, the fact has long been thoroughly established that the performance is very much improved by using low frequencies. Again, those who have used the motors with rotating field of the two-phase or three-phase type have all been obliged to reduce the frequency of the current to get the best results. In this connection I am pleased to be able to show a diagram giving some tests which were made for me of a three-phase motor at 41 complete periods per second, and at 56 periods per second.



It will be noticed that at 56 periods the maximum efficiency is given when the output is 17 H.P. It is then 85 per cent., and the efficiency at 41 periods per second at the same output is 87 per cent. But it will be noticed that the efficiency at the latter frequency goes on increasing until the output of the machine is 19½ H.P., when the efficiency rises to nearly 88 per cent. Thus, by lowering the frequency from 56 to 41 periods per second, not only had the output of the motor been increased 15 per cent., but the efficiency had also been increased 3 per cent. It is also found —which is a matter of the utmost importance—that in every self-starting alternating motor, whether multiphase or otherwise, the effort at starting is increased by lowering the frequency.

Again, I find that the ordinary direct-current motor with a laminated field works extremely well with low frequency; even without lamination of the field it works, though not well. I have consulted nearly every electrician of experience in this direction whom I have met during the last year or two, either in Europe or America, on this point, and they generally agree with me that the facilities of working motors of whatever kind are very much greater with a low frequency. Last year, being aware that Prof. Anthony had experimented considerably in the direction of series-wound motors with laminated field, I asked him his opinion, and he expressed himself as follows :—

"In reply to yours of August 30th, I have built two or three continuous-current machines with laminated fields to run with alternating currents, and have succeeded in running motors of about one-eighth H.P. directly from the Westinghouse converter, where the frequency is some 130 per second. Such small machines run very nicely where the alternations do not exceed 25 per second. In fact, so far as I have tested, they seem to give an output fully equal to what they will with continuous currents. Of course, with high frequencies the self-induction of the field is against their working, but at 8 per second I should say that large motors could be run with perfect success."

I wish to repeat that, from what I have seen in the workshops of all advanced electricians in the last year or two, I am confident that in the near future single-phase alternating-current motors, self-starting on full load will be largely used; and there is not the slightest doubt that all of these work far better with low frequencies. In fact, as Mr. Brush once said to me when I was discussing this matter with him, "Really, your best plan would be to lower the frequency so much that you get a direct current."

Whilst speaking of low frequency in relation to motors, I must say that I have much greater hopes of obtaining a good commutating device with a low frequency than with a high one; and I will also state that I have great hopes of important advantages coming to us from the invention of such a commutating appliance which will enable us to furnish street railway companies, electro-metallurgical works, and other consumers with the direct current without the use of any heavy revolving machinery at the transforming station.

I am not sure that it ought not to be said that the greatest advantage of low frequency is in connection with the conductors used for transmission, and in the parts of the apparatus that require high insulation. When a high frequency is used there are certain difficulties which are well known. The first of these has been strongly urged by Lord Kelvin, namely, that when using large conductors an alternating current of high frequency tends to confine itself to the outside of the conductor, thus increasing the total resistance. Attention was first generally directed to this subject by the Presidential Address of Prof. Hughes to this Institution. A second difficulty is that with high frequency the impedance of the line due to the magnetic field formed between the go and return wires may amount to a very sensible quantity. Attention has been drawn to these matters by Mr. A. E. Kennelly, and his Paper* on the subject should be carefully studied. Then, again, with high frequency there is a greater tendency to discharge from an electrified conductor into the air. This means that the insulating of a bare conductor is more difficult with a high than with a low frequency. Lodge and others have made this very manifest with exceptionally high frequencies, but the truth of the statement is well known by those who have experimented even with lower frequencies. Another trouble is that, whenever it is necessary to use solid insulation, a current of high frequency has a greater tendency to injure the insulation. Mr. Tesla has shown and explained so clearly the rapid deterioration of solid insulation by currents of enormously high frequency, that we cannot fail to see that advantage is gained by using currents of low frequency. Another very important fact is that with low frequency we are less troubled by the capacity of cables, and we have less loss of static charge accompanied by heating of the insulation. Again, the serious troubles which have been encountered at Deptford and elsewhere, owing to abnormal rises of electric pressure in the mains above the pressure generated by the dynamos, due to the resonant effect produced by the capacity of the cable and the self-induction of the circuit, may be reduced as much as we please by sufficiently lowering the frequency. All these facts are the explanation of what has been thoroughly established in actual practice, namely, that there are difficulties on the line when using high frequencies which tend to loss of power and to destruction of the insulation, and that these difficulties are largely mitigated, if not entirely obviated, by reduction of the frequency. It must also be remembered that, if we reach a frequency as low as 16 periods per second, any induction in neighbouring telephone circuits is utterly inappreciable by the ear. Finally, all eddy-currents diminish as the square of the frequency. Having now stated, as clearly as I can, what seemed to me the principal advantages of low frequency, I will place on the other side the disadvantages.

Besides the increased cost of transformers there is one fact which is apt at first sight to impress one as almost fatal to the employment of very low frequency, but which further consideration shows to be of little moment in the case of Niagara Falls: this is, that a low frequency is not suitable for electric lighting directly. But it must be remembered that it is decidedly preferable to use a direct current for arc lamps, and, in fact, in the present position of the art in America it would be almost a necessity. Hence the natural method of arc lighting would be to use the alternating current by means of a motor to drive the well-known arc lighting machines. In the course of the work at Niagara the first work in connection with arc lighting which will be set up is the lighting of Buffalo. At present this is done by means of steam engines, developing about 3,000 H.P., and driving arc lighting machines of the Brush, Thomson-Houston, and Wood types. There cannot be a doubt that, financially and practically, the best way of converting this station to enable them to use the power from Niagara Falls is to put in alternating motors in the place of the steam engines; and this will be the case in most of the towns which will be supplied with power from Niagara Falls.

It will be well at this point to say something about the frequency which is required to prevent the arc and incandescent lamps from flickering. I have made a number of experiments on these points, and my conclusions are as follows :—A 16-c.p. 50-volt incandescent lamp shows a flickering almost up to 25 periods per second, at which frequency the flickering ceases when at its normal brightness; but if pushed to an excess of incandescence, the flickering was just perceptible up to 27 or 28 periods. I believe that a 100-volt 16-c.p. lamp shows a perceptible flicker up to 28 periods; but I may mention that this flicker is not nearly so serious or perceptible as that which frequently arises from the employment of certain types of engines, especially single-acting high-speed engines, when sufficient fly-wheel momentum is not provided. As a case in point, I would mention the lighting in the Holland House, one of the best hotels in New York, where, to an experienced eye, the flicker of the lights in the large dining-room from this cause is very objectionable. The thinner the filament, the more liability is there to such a flickering. I have lately examined the thick filament lamps to which the name of "Bernstein" lamps has been given, which consume 6 to 10 amperes at low voltage. It takes so long a time for the incandescence to die out when the current is stopped, that I have little doubt about their being able to work without any perceptible flickering at so low a frequency as even 16 periods per second. I have also made some experiments of a similar nature on arc lamps at low frequencies. At 37½ periods

* Paper read before the Institution of Electrical Engineers November 9th.

* "Impedance," by A. E. Kennelly, American Institute of Electrical Engineers, April 18, 1893.

Digitized by Google

per second there was very bad flickering, and this was most noticeable when looking at a piece of white paper illuminated by the naked light, or when looking at an opal shade put on the lamp. At 40 periods it was still bad. Neither at this speed, nor at the previous one, was there any serious noise, but at 40 periods the noise could be perceived by putting a glass globe over the lamp resting on the metal framework directly. At 41·7 periods there was just enough flickering to be objectionable; at 45 periods it was just possible to notice it on a printed page held close to the lamp, but it was not visible when reading at a distance of 10ft. At 50 periods the only means of detecting anything of the sort was by looking directly at the arc; nothing was seen when reading a book, either with the opal shade on or off. At this frequency the noise became much more perceptible, especially with a long arc about one-eighth of an inch. On reducing the length of the arc to one-sixteenth of an inch the noise was much less. In all these experiments the consumption of energy was at the rate of 26 volts and 14·2 amperes at the lamp terminals. The best cored carbons of Siemens and Halske were used.

An objection has been raised to the use of low frequency owing to the fact that a periodical twisting strain is given to the shaft of the dynamo, but this objection disappears almost entirely when we are dealing with a machine generating two phases.

It follows, therefore, that for arc and incandescent lighting at a very low frequency it becomes necessary to use alternating-current motor-generators, or else to use something of the character of a commutating machine to convert into continuous currents. Such machines as those exhibited by Schuckert at Frankfort in 1891 are useful up to a certain extent, but they are expensive, and comparatively inefficient, as their only function is to commutate the current—an operation which ought not to involve any significant loss. At the present moment a good commutator for the alternating current is not upon the market, but the matter is of such prime importance that I feel confident that much will be done in this direction. In fact, I have seen enough with my own eyes to have no fear about our being able to generate continuous current from the two-phase alternating current without serious loss, and with very inexpensive machinery. If, however, the object of our work was mainly, or even to a considerable extent, to provide the means of lighting towns by arc and incandescent lamps, I should have hesitated to recommend a reduction in frequency below 42 periods per second, such as is used by Ganz and Co., and which is operated so successfully at Rome and Tivoli, and at a very large number of other places on the Continent. The officers of the Company and myself considered this matter most carefully, and, looking at the purposes for which our machinery is being set up, we felt sure that the proportion of electricity which would be used for lighting purposes would not be large, and that we must look upon our whole plant as a power producing and distributing plant, and that our object must be to distribute power in the most efficient and economical manner. This being the case, we agreed that it was desirable to lower the frequency so far as the mechanical conditions of the problem would allow. The lowest frequency which had been offered to us by the manufacturers was a very beautiful design of a machine at a frequency of 20 periods per second. This machine had admirable qualities, but was in some points not exactly adapted to the requirements of the situation, as developed by the selection of a special design for the turbine.

I have myself made several trials of designs at very low frequencies, even as low as eight and one-third periods per second, and for this frequency I prepared drawings of a machine which, though by no means perfect, shows a possibility of being worked into a sound machine of good mechanical construction; but further considerations led me entirely to modify the design of the machine, and eventually I arrived at the conclusion that, both from the point of view of design of the dynamo, and also for suitability of applying the current, 16 periods per second was probably as good as could be obtained. The manufacturers to whom the contract has been given were anxious to use a lower induction in the iron of the machine than that which I would have preferred, and this rendered the machine of 16 periods per seconds heavier than could be supported by the hydraulic piston which supports the whole weight of the turbine, vertical shaft, and revolving part of the dynamo. Consequently we have made a compromise, and are going to build our first three dynamos with a frequency of 25 periods per second. In concluding my remarks upon low frequency, I must again repeat that, from a purely practical and commercial point of view, one of the great advantages lies in the fact that for any special purpose for which a motor is required any ordinary direct-current motor may be altered so as to act as a synchronising alternating motor at a very small expenditure of time and money.

Electromotive force.

The question of selecting a suitable electric pressure for working to Buffalo, and also for local purposes, is of some importance. Generally speaking, it is desirable to use as high an electric pressure on the line as is consistent with safe and continuous working, as this effects a great saving in the amount of copper used on the line. In the first report, founded on insufficient data, which I wrote more than three years ago for the Cataract Construction Company, I recommended that 2,000 volts should be used in the neighbourhood, and that the pressure should be raised by means of transformers for the more distant transmission. But the greater portion of our work in the immediate future will have the character of distant transmission. In most of the tenders which were submitted to us the cost of transformers was almost as much as that of dynamos, in some it was more, so that the use of a step-up transformer for distant transmission meant almost double the cost of generating the current. I hold the view that a pressure of even 20,000 volts can be generated as safely in the dynamo machine itself as in the transformers, and that if we used 20,000 volts for the local work as well as for Buffalo we should not be incurring the additional expense and losses of a step-up transformer, while we should be saving enormously in the cost of copper. Unfortunately, American manufacturers have never supplied alternating-current dynamos at a higher pressure than 2,000 volts, and they are not practically acquainted with the experiences which have been gained in Europe at extra high pressures. Most of the manufacturers declared their inability positively under any conditions to go above 2,500 volts, although some of their engineers were willing to go as far as 5,000 volts. This, however, would have been no material gain to us; and the consequence is that to meet the views of the manufacturers in our preliminary work—that is to say, in the construction of the first three dynamos for our power-house—these will be only of such electrical pressure as they are accustomed to deal with. We shall, therefore, be using dynamos generating current at 2,000 volts, and employing step-up transformers for the extra high pressure. This may possibly render it desirable in our first work not to use the extra high pressure for local purposes. Besides the actual cost of the conductors a very serious matter arises when we are dealing with the large currents due to comparatively low electric pressure. I refer to the large quantity of copper which has to be put into the conductors. Working at 2,000 volts, each phase of each of our generators will give nearly 1,000 amperes without considering the effects of retardation of phase, which will increase the current by quite a perceptible amount. So that to put in the most economical section will require 3 sq. in. for each conductor or 12 sq. in. of copper for each 5,000-H.P. dynamo, or 36 sq. in. section of copper for the 15,000-H.P. which is now being supplied. When we remember that even with low frequency the question of skin resistance comes into play when the conductors have a large diameter, it is obvious that we are introducing serious troubles, and if a subway were to be made to carry these conductors it would require to be of very great dimensions. For these reasons I am still anxious to see the extra high pressure used, even for the factories within a distance of a mile. The uniformity of the system would undoubtedly be of great benefit to us if we could generate the whole current for all purposes at the same extra high electric pressure; but, as I have stated, we were obliged to content ourselves with a somewhat less perfect arrangement than would be adopted if we were dealing with the utilisation of a waterfall in Europe.

I wish to lay stress on the importance which I have considered to lie in the fact of having a perfectly uniform system with interchangeable dynamos. Many engineers to whom I have talked have suggested the use of special dynamos at different pressures for special purposes; but if we had a special dynamo for arc lighting, and another for incandescent lighting, a third for street railways, another for electro-deposition, and so on, the possibility of interchanging dynamos would disappear, and the whole system would be much more complicated to work.

I wish now to make a few remarks about the insulation which it has been customary to put upon dynamos and transformers which were to be used with high electric pressure. Many persons who have not given sufficient attention to the subject seem to be inclined to believe that there is something mysterious about the tendency of electricity in a dynamo or transformer to break through the insulation, and which prevents them from being subject to the ordinary laws of electricity. Thus, when building a dynamo for 2,000 volts a thickness of insulation is given which would stand a test of more than 100,000 volts without breaking down, and it has been found from the ordinary methods of using the plant that if something of this sort is not done the insulation will break down. I wish to point out that the reason for this lies in the fact, not that the insulation breaks down with 2,000 volts, but that in a 2,000-volt system, as generally used, electromotive forces are occasionally generated amounting to 100,000 volts or more. These abnormal rises in electric pressure are chiefly due to the resonant effect, which has received so much attention of late years, and may be caused by the sudden breaking of the circuit of the dynamo. If these causes of excess be avoided, the electric pressure will never rise above the working pressure, and the insulation will never break down, even though its thickness be only little more than sufficient

Digitized by Google

to stand a test at the working pressure. Dr. Fleming has shown us how to kill the resonant effect, and such a phenomenon never appears now at Deptford. This trouble may also be avoided by having as little capacity on the line as possible, especially when combined with low frequency. As to the cause of trouble mentioned above, I hold that it is a piece of culpable ignorance, ruinous to the machinery, if anyone should ever, on a large power circuit with alternating current, suddenly break the circuit while current is passing. This practice is quite unnecessary, and has given rise to a large proportion of the breakdowns of alternating-current machinery.

(*To be continued.*)

INSTITUTION OF ELECTRICAL ENGINEERS.

ANNUAL DINNER.

The fifth annual dinner of the Institution of Electrical Engineers was held on Wednesday at the Freemasons' Tavern, Mr. W. H. Preece, President of the Institution, in the chair. There were present the Right Hon. Arnold Morley, M.P., the Right Hon. A. J. Mundella, M.P., Prof. G. Carey Foster, Sir Jas. Crichton Browne, Mr. Jacob Brett, Dr. H. E. Armstrong, Prof. W. E. Ayrton, Mr. Latimer Clark, Prof. D. E. Hughes, Mr. J. Wolfe Barry, Prof. G. Forbes, Prof. A. W. Rücker, Prof. W. Crookes, Mr. W. H. M. Christie, Mr. G. Kapp, Sir Thos. Blomefield, Bart., Mr. F. J. S. Hopwood, Mr. W. M. Mordey, Mr. Jas. Swinburne, Mr. A. Wright, Prof. J. Perry, Sir David Salomons, Bart., Mr. Alexander Siemens, Mr. R. E. Crompton, Sir Hy. Mance, C.I.E., Mr. F. Bailey, Mr. Lamb, C.M.G., Mr. Macrory, Q.C., Hon. C. Dillon, Major Holden, R.A., and many others.

The toast of the Queen having been drunk,

The PRESIDENT proposed the toast of the "Learned Societies," coupled with the names of Sir James Crichton Browne and Prof. A. W. Rücker. By singling out a certain class of gentlemen as members of learned societies, they did not by any means wish to imply that the members of the Engineer's Society were unlearned, the distinction which they wished to make was between knowing and acting. There were many of them who were duplex members, and as regarded their guests, there was no doubt that in editorial quarters public officials were considered neither learned nor unlearned, taking up a zero position. The public man suffered very much, not so much from that which he said as from that which he did not say; he was subject to a fiend called the interviewer. There was also the portrait taker, and the biographer who brought to light not only all the things they did, but the things they did not do. The learned man, however, could retire calmly to his laboratory and think out problems, or rule in his class-room an attentive audience of students. There was no doubt that the practical man owed much to the theoretical man, but the theoretical man owed a good deal more to the practical man. Telegraphy, telephony, the electric light, and electric railways owed their development rather to practice than theory. However, theory kept them straight, and told them what to do, and the representatives of the learned societies were doing in their spheres an immense amount of service to the practical men. Sir James Crichton Browne was Vice-President of the Royal Institution, an institution to which he entirely owed his own presence there, as but for the early sparks of electrical lore impressed upon him by Faraday he did not believe he should ever have attained his present position. They were proud also to couple the toast with the name of Prof. Rücker, whose charms as a lecturer they were well acquainted with.

Sir JAMES CRICHTON BROWNE, in response, said that he could safely affirm that they regarded it as a compliment to have their position and work recognised by a body like the Electrical Engineers, and by all those engaged upon electric research, in regard to whom they, the learned societies, were standing on tip-toe eager to see what they were going to do for them next. They were full of gratitude and admiration towards them for their splendid achievements of recent years, but they had a lively sense of favours to come. The Electrical Engineers had festooned their homes with beatified glow-worms; they had stretched their ears—not in any asinine sense—so that they extended all over the town, and even as far as Paris; they kept them in sympathetic vibration with everything that was going on in the uttermost parts of the earth, and elevated or depressed them, as if phantom steeds worked by spectral machinery obeyed their behests; they had performed chemical transmutations like the alchemists; and they had treated them when they were ill like the Royal College of Physicians. They had vastly increased the comforts and conveniences of modern life, added enormously to the means of human communication, and afforded invaluable assistance to students and investigators in every department of science, and to find a parallel to their achievements of recent years, and the expectations they had gathered, it would be necessary to go back to the sixteenth century, when the discoveries Columbus helped

"To fill
The spacious times of great Elizabeth
With sounds that echo still."

When the annals of the present reign were written there would be no more brilliant chapter than the one that recorded the exploits of electrical engineers. As regards the Royal Institution he would only say that he thought it was worthily maintaining the great reputation it obtained by the labours of Davy, Faraday, and Tyndall; work was now being carried out in its laboratories which could not be carried out anywhere else, momentous scientific work of deep interest and far-reaching significance. He had hoped to meet Prof. Dewar there, but he understood he had gone down to St. Andrews to receive a well-earned academical honour.

Prof. RÜCKER said that there was no radical distinction between the learned societies and the Electrical Engineers Society. The pictures that were sometimes drawn both of the theoretical and the practical man contained as much truth as caricatures generally had. After all, the distinction between practical and theoretical work was not a distinction of subject but of the spirit; pure science might be cultivated in the spirit of commerce, and commerce in the spirit of science.

Prof. W. E. AYRTON proposed the toast of the "Engineering Societies," the toast being responded to by Sir FREDERICK BRAMWELL.

Mr. LATIMER CLARK then proposed "Our Guests." They were honoured by the presence of two members of the Government, both equally interested in engineering. He should like also to mention the name of Mr. Jacob Brett, who was undoubtedly the father of submarine telegraph, and who was with them there.

Mr. MORLEY expressed the opinion that no commercial undertaking, certainly no deparment of the State, was more dependent upon or interested in the successful development of electricity than that branch of the service with which the president was connected, and over which he himself had the honour to preside. It was common knowledge that the success of our telegraph and telephone systems was dependent upon the successful utilisation of electrical currents, and he did not think he claimed too much when he said, with regard to the first of those services, that we had at least taken the foremost place among the nations of the world, even if we were not entitled to claim that we had surpassed all other nations on both sides of the Atlantic, and that we had provided a service which was superior to that of any other country. A series of almost unprecedented storms had lately been experienced, and he was glad to be able to report that the telegraphic service of the country had almost without exception been uninterrupted by those serious disturbances. It was not so on the Continent, and two days ago, speaking telegraphically, had once again absorbed Calais within the Empire of Great Britain, because all telegraphic communication with Calais was for a time entirely suspended, except by the wire which connected Calais with London. He did not know that he could say so much with regard to our telephone system, but he had very little doubt that the time was not far distant when that system would be equal if not superior to the telephone of any other country.

Mr. MUNDELLA proposed the toast of "The Institution of Electrical Engineers." He took occasion to mention that the excellent work done by the Electrical Standards Committee had been approved generally by electricians throughout the world. France, Germany, and the United States were prepared to adopt them, and he was so much encouraged by all he heard of the prospects of an international arrangement that it would shortly be his duty to submit an Order in Council to Her Majesty adopting the electrical standards as the standards for this country, and he hoped for the civilised world. He acknowledged the indebtedness of the Board of Trade to the Institution, and cordially desired the development and extension of its operations.

The PRESIDENT, in reply, said he had been associated with that Institution since its start. The slope of energy ascended as they proceeded westward, and contact with the land of the prairie seemed to excite a mental activity, and except in regard to telegraphy they must seem small to their American cousins. Nothing grander had been seen than the World's Fair. They were making in this country great advances; their progress might be slow, but he thought that in the end it was sure, and they might find themselves at the very head. The electric light, he contended, was to become the poor man's light. He had announced that over and over again, and even now it was received with a slight amount of ridicule. Their trouble was that electric light was too cheap, and did not at present produce the revenue some of them had anticipated. Their Society on January 1, 1873, numbered 352 members; now they mustered 2,260, the average number of members per year joining them during the past six years being 225. Turning to the question of the future, there was nothing so sure to happen as the unexpected, but what it was no man could tell. Speech was being extended in all directions, and he saw no difficulty in speaking with America; and they might even be able to see their cousins at the Antipodes. Their Institution dealt with the present, and its object was to collect facts, to circulate truth, and to cement friendship, and when they were called upon by the great Departments of State to assist them in their deliberations, they would do everything in their power with all their hearts and souls to render them that assistance. The President of the Board of Trade might be quite certain that when he got back from them those rules and regulations which he thought they should be able to understand, they would try their very utmost to meet his difficulties, to put them into such a state that he would have no difficulty in understanding them.

The meeting then terminated.

Electricity in Mining.—A Paper presented at the recent Engineering Congress in Chicago stated that there were in the United States 300 mining companies using electricity. Several mines in Colorado are operated by electricity that could not be by steam, on account of their situation on the face of precipitous cliffs, up which the transportation of water and fuel would be nearly impossible.

LEGAL INTELLIGENCE.

The Medical Battery Company (Limited).

At Marlborough-street Police-court on Wednesday last, C. B. Harness, Managing Director of the Medical Battery Company; J. M. M'Cully, a physician, of Blandford Mansions, East-street, Marylebone; C. B. Hollier, a salesman, of Warley, Sussex; and Dudley Towers, a "masseur," were charged on remand, before Mr. Hannay, with having conspired, by fraudulent advertisements and otherwise, to defraud; also with having conspired to obtain by false pretences the sum of £52. 10s. from Col. Jeremiah Brewer, the sum of £2. 2s. from Theobald Burbage, and the sum of £2. 2s. from William Hibberdine Manners, in each case with intent to defraud.

Mr. Thomas Terrell prosecuted; Mr. Horace Avory appeared for Harness, Mr. A. R. Cluer for M'Cully, Mr. C. F. Gill for Hollier, and Mr. C. W. Inman for Towers. Detective-sergeant Weatherhead, D Division, watched the proceedings on behalf of the police.

WILLIAM LYND, an electrical engineer, said that he had been in practice since the year 1857. In 1887 he met Harness for the first time, who told him that he wanted a gentleman well up in electrical science to deliver a series of lectures on the applications of electricity. He said, "I will be perfectly frank with you; my electrical knowledge would go into a nutshell. I have built up a large business, have got a fine establishment, and if I am not on the right tack just tell me where I am wrong." He entered into an arrangement with Harness to give 12 or 14 lectures, and Harness agreed to pay £2. 2s. for each. On a subsequent occasion he had a conversation with Harness about the bills which were lying in bundles all over the premises, and advised him to make a genuine electric belt. Harness then said, "The belt is good enough for me, is good enough for the public, and all we have to do here is to sell the goods." Harness told him that the belts cost him 2s. 9d. each all round. They sold at that time from £1. 1s. to £5. 5s. each. He knew that Harness had absolutely no knowledge of electricity owing to the ridiculous questions that he asked. Once he inquired, "Do you get electricity from a dynamo by friction?" He had a conversation with Harness about his assistants, and Harness asked him not to talk to them about electricity, for it only embarrassed them. Harness told him that a pushing draper's assistant was a good man to employ because he knew how to sell the goods. In one of his lectures witness referred to distinguished electricians; after the lecture Harness called him on one side and said, "I don't want you to advertise such cattle. You must speak of Harness's electricity. Take my advice, science does not pay. If you will step down from your scientific pedestal to our level and help to sell the goods I will make your fortune." While witness was at the establishment, which was about four weeks, he never found anyone there that knew anything about electricity.

Cross-examined by Mr. GILL: His title to be called an electrical engineer rested upon the experience he had had in electricity. He was manager to J. Lewis Young, of Fore-street, and managed for them the Edison Photograph Department. He also delivered lectures on scientific subjects all over the country on his own account. He did not lecture upon electricity as being a means to cure disease. He did not sell electrical appliances. He had lectured against the appliance of the Harness belts because he wished to expose the fraud. He had for four years studied anatomy and physiology in relation to electricity. In one of his lectures he spoke generally of the advantages of electrical treatment, as applied at the establishment of Mr. Harness. When he was delivering his lectures he did not warn the audience that the brush which was sold downstairs was a bogus one. He meant to expose the affair after he had delivered the lectures he had contracted to give. He did not think that he referred to the "eye battery" in his lectures. He would not swear that he did not speak of it "as being admirably adapted for strengthening the optic nerve." He could not undertake after such a lapse of time to remember the details of his lectures.

Mrs. KATE WILCOCKS then gave evidence as to the effect of wearing one of Harness's belts.

Cross-examined by Mr. AVORY: Mr. Morris, the solicitor for the prosecution, undertook to take up her case for nothing. She did not know that in October, 1893, he had written to the Medical Battery Company claiming damages on her behalf.

The defendants were formally remanded for a week.

The petition against the Medical Battery Company (Limited) came again before Mr. Justice Vaughan-Williams on Wednesday. The petition had been amended by asking alternatively for a compulsory or a supervision order.

After hearing counsel for and against the petition,

His LORDSHIP said he considered it his duty to take care that the case should not be determined by any topics of prejudice or matters foreign to the liquidation proceedings. When the petition was first presented no resolution was passed for voluntary liquidation, but a debenture-holders' action was commenced, in which a receiver was appointed. Subsequently a resolution was passed that the Company could not by reason of its liabilities go on, that it should be voluntarily wound up, and that Mr. Davis, an accountant, should be appointed liquidator. So far as the police court investigation at Marlborough-street was concerned, that ought not to be held to be a ground for saying that the creditors would be prejudiced by the continuance of a voluntary winding-up. The Company had obviously been under the conduct of one man, and the affidavits produced went to show that Harness dealt with the affairs of the Company in a way which was unusual. However creditable it might be that Harness and others should desire that the new Preference shareholders should not suffer, still, there was no right to return their money. It would be very prejudicial to the interests of the creditors that the liquidation should continue under the control of the shareholders, especially as the receiver in the debenture-holders' action was to continue in office, he being the nominee of the shareholders. Under the circumstances the Court would make a compulsory winding-up order.

Elieson Accumulator Syndicate v. the Earl of Galloway.

This case was heard before Mr. Justice Kennedy, without a jury, some days ago, and was reported in our last issue.

His Lordship gave judgment on Wednesday. He said he was of opinion, firstly, that there was no such Company; and, secondly, that, even if there had been a valid application by the defendant for shares, there was a withdrawal of it before there was any acceptance by the Company. Upon either of these grounds the defendant would be entitled to succeed in this action.

CORRESPONDENCE.

THE CANDLE-POWER OF ARC LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the editorial remarks on the candle-power of search lights, I am very sorry that you should have so thoroughly misunderstood the meaning of my letter as to assume that I referred to the surface illumination produced by the beam of light. I precisely meant the candle-power of the search light as measured in the same way as it is done with any incandescent lamp, for instance, by phometric tests at a distance sufficiently large to make the diameter of the light negligible against the distance, so as to make the law of inverse squares applicable.

I think I can trace the source of this error in your editorial remark to a mistake as to the nature of the rays emitted by the light, an error which, by the way, is frequently made. You seem to assume that the rays of the search light are naturally parallel, and that what there is of divergence is due to irregularities, &c. This would, indeed, be true if the light-giving source were a mathematical point in coincidence with the focus. Since, however, the crater of the arc is not a point, but an area, there exists a true divergence in the rays of the search light, and the rays issue from the reflector, not mainly in one direction only as a parallel beam, as you state in your remark, but about uniformly in all directions within a small spherical angle, the angle of divergence of the beam. The result hereof is that the diameter of the beam—except in the immediate neighbourhood of the reflector—is proportional to the distance from the reflector. Hence the illuminating power is inversely proportional to the square of this distance, and the search light acts similar to an ordinary arc lamp, with a screen with a round small hole in front of the lamp, which permits only a beam of small angular diameter to pass, but by no means a beam of parallel rays.

It is certainly not possible, in the short space of a letter, to give a complete treatise on the search light, correcting, for instance, the further error you make in your editorial, that only the solid angle subtended by the reflector needs to be considered, and that the large size of the reflector is, therefore, only for the purpose of avoiding shadows, &c.

I may refer you, however, to a short treatise on this question by Mr. F. Nerz, published in your own paper, *The Electrician*, where I hope you will find all the explanation necessary to understand the fact that the photometrically observed candle-power are, within the beam of light, really of such magnitudes.—Yours, &c.,

November 7, 1893. CHARLES PROTEUS STEINMETZ.

[The "further error" alluded to in the last paragraph but one of the above letter relates to a Note on a totally different subject, viz., the Paper by Mr. B. A. Dobson, on "Artificial Lighting of Workshops." The remainder of the letter is dealt with in our Notes.—ED. *E.*]

A Turin correspondent, asking for information respecting the working of the Rockport-Nova Scotia cable, belonging to the Commercial Cable Company, is referred to Mr. F. Jacob, Ellsdene, Beaconsfield-road, Westcombe Park, London, S.E.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES' DIRECTORY AND HANDBOOK" contains over 1,000 pages, several new and handy features having been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

The 1894 Edition is in preparation, and will be published in January next. New names, alterations of addresses, &c., are received at any time, but the Directory blanks and circulars are not sent out until later in the year, in order that the most recent, and consequently the *correct*, addresses *only* shall appear in the book. Full printed particulars can be obtained, post free, from "The Publisher," *Electrician* Office.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, which has a special interest at the present time, is now ready, and will be forwarded on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus can be obtained on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready, and will be sent direct on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus will be forwarded free on application.

TENDERS INVITED.—The Barnet Local Board invite applications from companies or firms willing to take a transfer of, and to undertake and carry out, the powers granted by the Barnet Electric Lighting Order, 1893. Applications must reach Mr. H. W. Poole. the clerk to the Local Board, not later than December 30th. Further particulars appear in our advertisement columns.

——— The Corporation of Belfast invite, in our advertisement columns, tenders for various work in connection with their Electric Lighting Station. There are eight contracts—for gas engines and dynamos, switchboards and connections, batteries, laying of concrete culverts, cast-iron work, insulators, insulated cable, and copper strip respectively. Copies of the specifications can be obtained from Prof. A. B. W. Kennedy, 19, Little Queen-street, Westminster, S.W., or from Mr. Samuel Black, the town clerk of Belfast. Tenders must reach the latter gentleman not later than Friday, December 15th.

——— The Directors of the North-Eastern Railway Company require tenders for the supply of telegraphic apparatus and telegraph wire and line stores during the six months ending June 30th next. Tenders must be in by December 5th.

TENDERS RECEIVED.—A considerable number of tenders have been received by the Sunderland Corporation Highways Committee for the necessary works for the lighting of the town by electricity. A Sub-Committee has charge of the tenders, and will report to the Committee thereon.

APPOINTMENTS.—Mr. J. D. Bailie (late Installation Superintendent for Messrs. J. D. F. Andrews and Co.) has been appointed Yorkshire Representative for Messrs. C. A. Parsons and Co., of Newcastle-on-Tyne, with offices at Peacock's Buildings, Park-row, Leeds.

——— Messrs. Lazare Weiller and Co., of Paris and Angoulême (France) have appointed Mr. Fernand Espir their sole agent for the United Kingdom and the Colonies for their high conductivity copper wire and strip for electrical purposes.

LIQUIDATIONS.—A meeting of the members of the United Telephone Company of Rosario (Limited) will be held at 78, Coleman-street, London, E.C., on December 18th, at noon, for the purpose of receiving an account of the winding up.

——— The first meetings of creditors and contributories of Elmore's French Patent Copper Depositing Company (Limited) will be held on December 5th, at 12 and 2 p.m. respectively, at the Holborn Restaurant, High Holborn, W.C.

DISSOLUTION OF PARTNERSHIP.—The partnership between William Retallack and Alfred West Thorpe, carrying on business as electrical manufacturers at 36, Moorgate-street, E.C., under the style of Player and Retallack, has been dissolved.

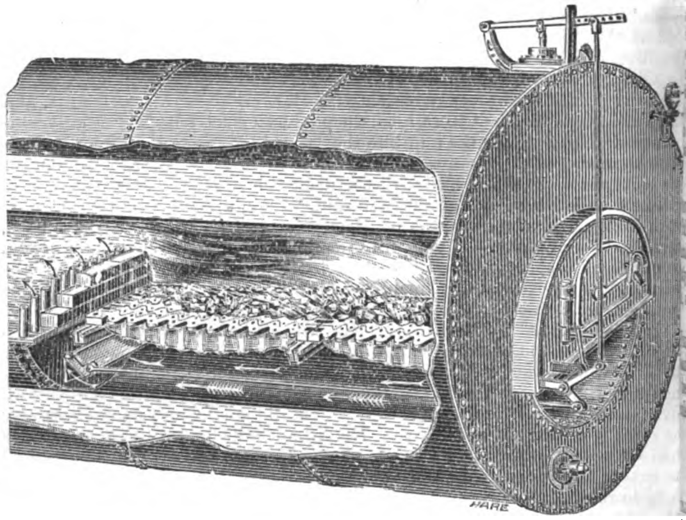
MESSRS. DRAKE AND GORHAM.—As the result of the installation which this firm reconstructed at Effingham for Mr. Czarnikow some years back, they have been entrusted with the extensions at his town house, 103, Eaton-square, and City offices at 29, Mincing-lane. They have also successfully completed the installation of the electric light at Chatsworth, the seat of the Duke of Devonshire.

OMNIBUS AND TRAMCAR LIGHTING.—The Omnibus and Tramcar Electric Lighting Company (Limited) advertise that they are prepared to receive applications for lighting private vehicles under Pitkin's patents, which, the company state, are now supplied on the London street tramways, many of the London General Omnibus Company's vehicles, and a number of private omnibuses.

EXHIBITIONS.—There is to be an International and Colonial Exhibition held at Lyons, France, in 1894, which has the support of the French Government and of the leading Chambers of Commerce throughout France. Applications for space for this exhibition are now being received by Mr. Brandreth, of the Anglo-Continental Contract Association (Limited), 52, Queen Victoria-street, E.C., from whom all further particulars can be obtained. There is to be a British Section at the exhibition.

——— A Mining and Metallurgical Exhibition is to be held at Santiago, Chili, during the year 1894, consisting of eight sections—motive power, electricity, extraction machinery, mechanical preparation of minerals, metallurgy, chemical industries, statistics and plans, and production of the working of mines and metallurgy.

MESSRS. CLARKE AND CO.'S FURNACE BARS.—The patent furnace bars which are specially manufactured by Messrs. Clarke and Co. of Forest-road, Nottingham, and of which an illustration is here given, are said to answer in every way all that is required of them.



It is claimed that as one of these bars fills the space of two of the ordinary kind, and as they are much lighter in weight, the price is little more than for ordinary bars per square foot. At present the firm have supplied eight asylums, including Lincoln County Asylum; Durham County Asylum, Sedgefield; Royal Medical College, Epsom, &c.; the workhouses of Lincoln, Barnstaple, and Ross; and the Dublin Science and Art Museum, Exeter Corporation Offices, Leeds Hospital, and the Nottingham Hospital.

MICA.—We have received from the Lake Girard System of Mines, of Ottawa (Canada), specimens of amber mica, obtained from the company's mines, which they claim to be the largest in the American Continent, and of which they hold a stock of over 1,000 tons.

MANCHESTER SHIP CANAL.—Mr. W. Morton, of Warrington, has, during the past few months, had charge of an electric light plant for night work on the Acton-Grange section of the Manchester Ship Canal, during the process of cutting through the old railway recently given over by the London and North-Western Railway Company. The plant, which comprises a horizontal engine coupled to a dynamo, has supplied light to 12 2,000 c.p. arc lamps, and has been in constant use nightly, enabling the work to be carried on without interruption. Mr. John Jackson, of Westminster, the contractor for the Canal, receives, we understand, a handsome premium for executing this branch of the contract in so short a time.

COLLIERY LIGHTING.—Messrs. Ernest Scott and Mountain (Ltd.) are supplying an electric light plant for the Coltness Iron Company's colliery at Newmains, Lanarkshire. The installation is to include above and below ground, and the lighting of thirty-four workmen's cottages. An electric pumping plant, capable of delivering 100 gallons of water per minute from the river to the colliery, is also to be supplied by the firm.

A New Microphone.—To make fun of a mistranslation is generally in bad taste. Our excuse for printing the following as we received it is that considerably greater attention will probably be given to it by our readers than if we attempted to put it into English; the intentions of the makers will thus be served. The style gains additional piquancy from the fact that Prof. Von Helmholtz is a perfect master of the English language :—

Establishment for Telegraphic and Telephonic Constructions. Propr., Hammacher and Paetzold, at Berlin, O., Andreas-str. 32. Assented extract from the report of H. J. M.'s Physic-Technic Institute of German Empire as to our quite new by the Patent Office privileged Microphone :—

Charlottenbourg (near Berlin), February 27th of 1893.

This microphone presents constructed very differently from that organisation of the ordinary telephonic stations: It is furnished, to receive sounds, with a thin carbonic plate of 5,5 c m. thickness, that 4 wadcylinders are leaning upon pretended to be filled up with coal dust and connected backwards with another stronger carbonic plate. Particularly the trials extended too to observe the degree of acoustic intensity and distinctness in reproducing by the farhearer of the second station the words pronounced towards the principal station of the microphone, even when the electric current furnished by one or two accumulating cells in the microphone be diminished by diverse resistances intercalated and even the resistance of the transmission between both the apparatusses be raised too. The current's force was appointed with a Weston-Tensivmeter put against an intercalate resistance of 10 Ohm. In applicating intensities of 0,02 up to 0,04 ampere the words pronounced close on the microphone were heard at the other extremity louder than it may be wished for ordinary telephonic communications and may well be understood, even when pronounced in but ordinary conversational manner in a distance of 3 meters from the apparatus. The intensity of the current may be lowered, by means of ballasting resistance to one milliampere without claiming extraordinarily raised voice to facilitate communicating through both the apparatusses. But when reduced to half a milliampere the intensity is debilitating in surh a manner that the voice cannot distinctly be understood. Parallelled with this microphone the other hitherto usuac ones are claiming at least the tenfold intensities of currents in the microphone to reproduce the voice by the far-hearer in the same loudness. This experience proves that the presented apparatus requires but a minimum of current in the microphone even to reproduce the transmitted voice with rather high loudness, and by consequence the battery as well as the microphone-contacts by longer use never will wear out, but present always favorable results. For its high intensity of sound it seems to be well fit for communicating from rather remote distances too.—(Signed) Von Helmholtz.

Installation Work Rules.—We have received from the St. James' and Pall Mall Electric Light Company (Limited) a copy of the latest installation work rules issued by the Company. The rules are neatly printed, mounted and varnished on a stout card 15in. by 18in., and are provided with a hanger.

Messrs. Felten and Guilleaume.—We have received from this firm a beautiful photo-lithographic picture of a train laden with 110 tons of their 5⅛in. wire rope, in one length of 33,000 yards. The rope is coiled in long hanks upon eight 8-wheel bogie trucks.

Chesterfield.—The Town Council have decided to apply for a Provisional Order.

City of London Union.—The Board of Guardians have requested their Consulting Electrical Engineer to advise the Infirmary Committee as to the expediency of lighting the building by electricity.

Clonmel.—The Corporation have decided to apply to the Board of Trade for a Provisional Order.

Derby.—The Corporation have decided to apply to the Local Government Board for permission to borrow £5,000 for the extension of the electric lighting works.

Ealing.—At the last meeting of the Local Board the question of issuing stock in order to raise the £25,000 which it is proposed to obtain for carrying out the electric lighting scheme came up for consideration, but it was thought desirable to postpone the question until the consent of the Local Government Board had been obtained to the expenditure on the works.

Edinburgh.—At a meeting of the Town Council on Tuesday Councillor Mortimer moved disapproval of the minutes of a meeting held on October 31st, at which it was resolved to light certain portions of the city by means of electric light. He objected to the electric light going out to the Dean Bridge when such important streets as George-street were not proposed to be lit by it. Lord Provost Russell moved the adoption of the minutes, which was seconded by Councillor Walker. Councillor Mackenzie, a member of the Electric Lighting Committee, submitted statistics showing the difference in cost between lighting by gas and electric lighting in the various streets comprised in the proposed area. There would be displaced by the electric light, if it was carried out, 782 gas burners, which cost £1,310. 4s. 9d. If they deducted from that the office expenses, which represented £68, being 1s. 10d. per burner, the total saving in cost would be £1,241. 16s. 9d., while 148 or 150 arc lamps would cost £2,960, making an additional cost of £1,718. 3s. 3d. But there was a patent which was being applied to arc lamps, which would, Prof. Kennedy said, permit them to turn off the light half-way, and that would save, perhaps, from £600 to £700 per annum. Mr. John Jamieson said he believed the difference in cost between the two lights would be £1,800, but the electric light would give 12 or 15 times the amount of light. He strongly contended that it would not be possible to improve upon what they had proposed as an electric light area. In reply to Councillor Cranston, Councillor Mackenzie stated that by the wires which would be laid along the streets no provision would be made for the lighting of shopkeepers' premises. The Lord Provost remarked that within the compulsory area they must supply shopkeepers, but the Provisional Order did not include all the street lighting. They were advised by the Cleaning and Lighting Committee to run out the electric light beyond the compulsory area. After further discussion, a division resulted in the minutes being adopted by 26 votes to 9.

Hanley.—The scheme for the lighting of Hanley by electricity is making headway, and according to Mr. Joseph Lobley, borough surveyor, there seems every probability of the central station being ready for work early in the new year. The buildings are nearly completed, and the machinery is ready for putting in. The mains have been laid throughout the cumpulsory area, and the supply mains of the works are now in hand.

Islington.—At the last meeting of the Vestry the Special Electric Lighting Committee reported that they had made exhaustive inquiries as to a site for the proposed central station, and had come to the conclusion that a site on the Great Northern Rail way Company's property in Eden-grove and Bernard-place was the best and most suitable they had seen. The Railway Company were willing to sell the site to the Vestry, and the Committee recommended that they be permitted to carry out negotiations for the purchase of the site. After a short discussion the report was adopted almost unanimously.

Liverpool.—Telephonic communication has lately been established for the Corporation of Liverpool, connecting the offices of the Water Engineer in Dale-street, Liverpool, with the water supplies of Lake Vyrnwy (Montgomeryshire), the Rivington Reservoirs (North Lancashire), and the houses of the reservoir keepers and walksmen along the lines of aqueducts. The work has been carried out to the specification of the City Water Engineer (Mr. J. Parry, M.Inst.C.E.), the contract for the complete installation being carried out by Messrs. W. A. Shaw and Co., of Stockport. The system is entirely on the metallic circuit principle, and the wires are carried as nearly as possible along the lines of aqueducts. The total distance of lines as laid is about 115 miles. The line wire is throughout of 12½ copper, and about 16½ tons of this wire have been used on the work. There are in all 26 stations connected on the system.

Moss Side.—At a meeting of the Local Board on Monday, the Sub-Committee appointed by the General Purposes Committee to make inquiries in reference to electric lighting, reported that they were of opinion that the Board should have the advice of an expert. The Board adopted the report and also a suggestion of the Committee that the proposed application of the Collier Marr Telephone and Electrical Engineering Company for a licence and Provisional Order be opposed by the Board.

Poplar.—The Board of Works last week decided to invite Mr. W. H. Preece to report, at an expense not exceeding 50gs., upon the question of electric lighting and upon the application of the Poplar Electric Lighting Order, 1893, to the district, with particulars of the cost of the installation of the light.

Royal Exchange.—Yesterday afternoon the Lord Mayor performed the ceremony of turning on, for the first time, the electric light at the Royal Exchange. Messrs. J. G. Statter and Co. have carried out the lighting, which comprises eight lamps, viz., four 2,500-c.p. 15-ampere Brockie-Pell arc, and four 100-c.p. Ediswan incandescence lamps. The wiring is carried out with lead-covered cables, with cast iron junction boxes, filled in with bitumen. The current is taken from the mains of the City of London Electric Lighting Company.

St. Asaph.—We understand that some of the principal tradesmen are in negotiation with a firm of electricians with respect to the installation of the electric light, and if sufficient support can be obtained an application will shortly be made for a Provisional Order.

Southampton.—At the Southampton Harbour Board meeting on Tuesday, the Works Committee reported that the Sub-Committee on October 26th witnessed the lifting and slewing of the electric crane, with a weight of three tons in the slings, and

Digitized by Google

afterwards the crane was put through severe tests, both as to speed and weight, and both lifting and slewing. All the tests required by the specification were satisfactorily carried out, the speed being in excess of that specified. A report was also received from Mr. J. G. W. Aldridge, the electrical engineer, thereon, with a table of results. He did not certify that day for the crane, as there were some minor points requiring attention by the contractors. The report was adopted.

SWANSEA.—Notice having been given by several companies of their intention to apply to the Board of Trade for a Provisional Order, the Town Council at their last meeting resolved to oppose each application, and to at once carry into effect the provisions of the Electric Lighting Order obtained by the Corporation in 1889.

WHITEHAVEN.—The public lighting and that of a number of business premises at Whitehaven is now done by electricity, the current having been fully turned on last week.

YORK.—At the last meeting of the Town Council some exception was taken to the visits made by the Street and Buildings Committee to inspect the electric lighting stations at Scarborough and Huddersfield. After a lengthy discussion it was resolved as follows:—"That whilst fully acquitting the Streets and Buildings Committee of any irregularity, this Council is of opinion that all expenses of this Committee on city business should be defrayed out of the rates of the city."

COMPANIES' MEETINGS.

Elmore's Patent Copper Depositing Company (Limited).

The fourth ordinary general meeting of this Company was held at the Cannon-street Hotel, London, on Wednesday, under the presidency of Mr. J. Todhunter.

The SECRETARY (Mr. L. J. Langmead) having read the notice calling the meeting,

The CHAIRMAN, in moving the adoption of the report, said that the position of the Company was stated in the balance-sheet as truly and completely as had been possible. He did not think there were many omissions, but when the present Directors took office, the condition of the accounts was such that it was only with extreme difficulty that they arrived eventually at the real position of the Company's finances. There were, in fact, certain undoubted liabilities which did not appear on the books at all, and which it was impossible for them to ascertain at once. The balance-sheet now submitted was that of the past year, for which the present Directors were not responsible. The capital had been increased by the Preference shares, which were issued by the late Board; otherwise the capital account remained practically the same as before, excepting that the royalties received for the copper sheet licences had been reduced by the £1,250 which came into revenue for last year. On the other side of the balance-sheet the land was the same, but the items of buildings and of plant and machinery had received certain additions. The amount written off for depreciation was insisted on by the auditors, and was in the same proportion as that written off in the previous year. The stock-in-trade was slightly increased, and the balance of loss was very considerably augmented. He believed they had now really written off pretty nearly everything that ought to be written off. They only took office on May 26th, and the balance-sheet was prepared on June 30th. After that they had a very short time to organise the factory and put things in order before they were brought face to face with the coal strike, which had ruined many manufacturers in the very district in which the Company worked. They had to face the position of affairs, however, and say whether they would close the works, and thus save expense, or use their utmost endeavours to carry on the works and execute the orders in hand. This was a matter of very serious consideration. The shareholders knew perfectly well what had been the history of the Company before—that excuses had been offered in all directions for work that was not done; and they felt that if they were again to be in the position of offering excuses instead of executing orders, they might as well close the works and for good. They took the course which commended itself to them, and used their utmost endeavours to obtain a supply of coal. They would not have been able to do this but for the intervention of their colleague, Mr. Dale, who was largely interested in the Durham district, and who obtained coal for the Company on exceptionally good terms. They, however, received it only in driblets, and only after great delay and difficulty; but, except on two occasions, they had coal enough to keep their works going, and to an extent sufficient to enable them to execute all pressing orders. No one demanded from them goods which had been ordered without obtaining them. This had involved them in considerable outlay; but they felt that it must be done at any cost. Another source of great anxiety had been their position with respect to the Wire Company. On the last occasion on which he addressed them a question was asked whether they could carry on the Depositing Company alone without the Wire Company. He replied that he thought so, but that it would be very difficult. Further experience, however, had shown him that they were absolutely dependent on the use of the furnaces on the Wire Company's premises for their copper. There had been a fear that the finances of the Wire Company were in such a position that the works would not continue under the control of the present Board of that Company; but he hoped that this matter had now been arranged. There was a debt owing by the Wire Company to this Company, and there was also a bill drawn by the Depositing Company before he was connected with it on the Wire Company. This bill was dishonoured by the latter, and the Depositing Company were bound to pay it. The bill was for £1,000, and the Wire Company became creditors to them for this amount. Shareholders in this Company generally held shares in the Wire Company, and they would know that a sum of £6,000 was raised in debentures by the Wire Company to pay off their creditors. At that time the Directors were called into consultation with the Board of the Wire Company, who engaged with them that the Depositing Company's debt should be liquidated by the Wire Company giving to them copper they had on their works which was of no use to them, and which would amount practically to the sum due to the Depositing Company. Owing, however, he was sorry to say, to a very serious mistake on the part of the trustees appointed under that arrangement, that engagement was not carried out, and the Depositing Company had not received the copper in question, nor had they been paid their debt. The capital possessed by the Company at the time the present Directors took office was reduced by £2,000 in consequence of the non-fulfilment of the Wire Company's engagements to them. With respect to the condition of the Company's works at the present time, they had expended very much less than they thought would be necessary in putting the machinery and works into absolute order. They were now in good condition, and they would be able to execute large orders when they got their coal. He thought that his colleague, Mr. Owen Jones, who had been spending a great deal of time on the works, would be able to tell the meeting that they were now really in such a condition that there was no doubt they would be able to turn out very large quantities of finished tubes as soon as they got the coal they required. Then came the question of orders. He believed that the shareholders, like himself, had been more or less sceptical as regarded promises for their goods, but they had now passed from a state of promise into a state of certainty. They had now on their books absolute orders in hand, which they could execute as they were able, to the extent of 65 tons of finished output. The larger proportion of these orders had come in within the last six weeks or two months, so while they had been practically idle at the works they had not been idle in putting forward the experimental tubes so as to obtain orders. He might tell them that the large shipbuilders in the North—most of the large firms—had had experimental tubes, which had been tested on the Company's works, sent to them to experiment upon, and these tubes had stood all the tests required of them. The consequence was that the Company had obtained from some of these firms very large orders indeed for these tubes, and they had not the least doubt that they would continue getting very large orders for them. They had also been approached by some very large firms who made the shafts for the great ocean steamers. He had satisfied himself on this point—that these firms were clearly of opinion that it would be the Company's process, and the Company's process only, that would cope with the great difficulty of coating the shafts of big steamers. If the coating of these shafts turned out satisfactorily, an immense trade was opened out for the Company, apart from the trade they had expected hitherto. This was a question for the future, but it was a question which shareholders must, he thought, consider extremely satisfactory, and one holding out great promises of extended trade. He had no doubt now that they had orders in hand and in prospect sufficient to keep their works going at their full capacity when they got the coal. At the time the strike occurred they had no idea that it was going to last four or five months, but if they had known this, he was sure that the policy they had adopted was the only policy they could pursue so as to preserve their business. The result of the action which they had taken had been that they had preserved their business and their credit, and had executed every order almost that was pressing at that time. He reckoned, however, that it had cost them between £3,000 and £4,000 to do this. When the present Directors took over the management the whole of the working capital was not more than £9,000 or £10,000, and deducting from this the £3,000 or £4,000 they had lost by the coal strike, the sum paid on behalf of the Wire Company, and the sum of between £600 and £700 which they had had to pay for liabilities not down on the list of creditors when they took over the Company's affairs they would see that the working capital had been reduced to about £4,000, which was absolutely inadequate to provide for the working of such a Company as theirs. He was extremely sorry to come before the shareholders of any Elmore Company with a tale of woe, to which they had been made so accustomed in past years; but he thought he should have their sympathy on that occasion, for they knew perfectly well that what had occurred to the Company in connection with the coal strike was absolutely unavoidable. It now rested with the shareholders to say whether they would provide the further capital which was necessary to carry on the works, now that the position was such that they seemed to see their way, or whether they would let the matter drop. His confidence was unabated, and he was sure that if it had not been for the coal strike they would have been able to go on without any more money. Prior to the strike in July the absolutely finished output from the works had been increased from about one ton per week to two and a-half tons, and this was at the time gradually going on. If they had got the output up to three tons per week he believed it would have met all expenses and have made the concern self-supporting. During the coal strike they had only been able to keep up the output with the greatest exertion to one and a-quarter ton. From the commencement of the coal strike the output fell off, but they believed that if it had not been for the strike they would have been able to have gradually increased the output up to ten or twelve tons a week, and this would have paid them very well. If they obtained money sufficient to carry on, he

could tell them, from what he had seen and what he believed, that they had a good business, and that it only required diligent work and sufficient material to enable them to turn the corner and do well. His proposal was a very simple one. Their capital of £200,000 had been fully subscribed, excepting as regarded 195 of the Preference shares. They had only one means of raising the money they required, which was by debentures. It must be remembered that they paid off debentures of £5,000, forming part of the Company's liabilities when the present Directors took office. They thought it would be unwise merely to issue these debentures again, because if they had to issue more debentures afterwards they would have to be of another class—second debentures. In view of the possibility of orders being received for the coating of shafts of ocean steamers an increased outlay on machinery would be required, and the Directors would not like to be without a little money for this purpose. They therefore proposed that the issue of debentures should be for £10,000, and that they should bear 6 per cent. interest. This amount would enable them to carry on their works and to set their business on a firm and sound basis. He would put his name down for £500 of the debentures, and including this amount there had been promises already to the extent of £1,300. They thought the debentures should run for five years, with an option to the Company to pay them off, on giving six months' notice, at 102. The position of the Wire Company he might describe as one of "suspended animation," and as a sort of menace to this Company. He thought he would have the support and sympathy of Mr. Atkinson in remarking that the time must come before long when a very strong effort must be made to liberate the Wire Company from its position of menace and to set its works going. His (the speaker's) view was that the two Companies ought not to have been separated, which he believed had only been done for speculative purposes. He might add that the capital of their own Company would have to be written down before any dividend would be paid. The amount now standing to the debit of profit and loss was £21,500, and they had also £11,958 standing as the value of the Wire Company's shares, which were worthless. The two sums made £34,000, which would have to be paid off before a shilling of dividend could be distributed to the shareholders; and they wanted to be able to pay the Preference dividend, at any rate, if they earned it. The shareholders need not suppose that the Company was in any sort of difficulty. They had capital and copper sufficient to go on with, but they had not money enough or copper enough to execute the orders in hand and in prospect. They could, however, go on with the works, though not at a profit in their present circumstances.

Mr. J. W. DALE seconded the resolution, remarking that he could endorse everything that the Chairman had said.

Mr. EWEN said that, in his opinion, the amount mentioned by the Chairman was by no means unreasonable, and he was himself prepared to take up his proportion.

Mr. J. ATKINSON expressed his approval of the way in which the business was being conducted by the Directors. He hoped that in a few days the Wire Company would be able to deliver the copper which they had promised. He had been glad to hear the Chairman express the view which he had himself always held, namely, that the two Companies ought never to have been separated.

In answer to Mr. SHURMER (the late secretary of the Company), who said that he did not believe that any Court would entertain a proposal, in the present condition of things, to reduce the capital of the Company,

The CHAIRMAN stated that this question had merely been brought before the shareholders in order that they might understand the position. It was not, however, proposed to take any steps at present in the matter, and the shareholders would be communicated with when the time came.

The report was then unanimously adopted, and resolutions were afterwards passed re-electing Mr. Todhunter to his seat at the Board, and appointing Mr. Close, of Leeds, auditor.

The proceedings terminated with a cordial vote of thanks to the Chairman and Directors.

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, *pages* 320-348, *&c., &c.*]

JOHN BIRCH AND CO. (LIMITED).—This Company has been registered, with a capital of £40,000, in £10 shares, to carry on business as engineers and contractors, as hitherto carried on by John Birch and Co.

J. DEFRIES AND SONS (LIMITED).—This Company was registered on November 18, 1893, with a capital of £100,000, in £100 shares, to acquire, take over, and carry on the business of chandelier, glass, and earthenware manufacturers, gas, electrical, and general engineers, illuminating contractors, &c., carried on by the firm of J. Defries and Sons, at 147, Houndsditch, London, E.C.

ALF. DOUGILL AND CO. (LIMITED).—This Company was registered on November 14, 1893, with a capital of £12,000, in £5 shares, to purchase or otherwise acquire, take over as a going concern and carry on in all its branches the business of engineer, ironfounder, gas engine maker, electrical crane maker, &c., carried on by Alfred Dougill at Leeds, Yorkshire.

EDWARD HOWELL AND CO. (LIMITED).—This Company has been registered, with a capital of £15,000, in £10 shares, to acquire and carry on the business of engineers and ironfounders, as hitherto carried on at the Waterloo Ironworks, West Quay-road, Poole, Dorset.

GORSEINON ELECTRIC LIGHT COMPANY (LIMITED).—This Company was registered on November 17th, with a capital of £1,000, in £1 shares, to carry on the business of electric lighting in all its branches, and for such purpose to purchase or otherwise acquire all necessary machinery to lay down, establish, fix, and carry out all necessary cables, wires, lines, accumulators, lamps, and works, and to generate, accumulate, distribute, and supply electricity in and about the Town of Gorseinon, near Swansea, Glamorgan.

ALADDIN PRIMARY ELECTRIC BATTERY COMPANY (LIMITED).—The annual return just filed shows that the whole nominal capital of £6,000, in £10 shares, has been taken up, of which 440 shares were issued as fully paid to Theophilus Coad, the vendor. The full amounts have been called and paid on the remaining 160 shares. At meetings, held September 5 and 22, 1893, the shareholders resolved to raise the limit in the number of Directors from five to ten.

ARIEL COMPANY (LIMITED).—This Company has just entered into an agreement with Samuel S. Allen, of 52, Woodstock-road, Bedford Park, Chiswick, London, W., for the acquisition of certain property (particulars of which do not transpire), and in consideration therefor have agreed to pay the vendor £1,000 in cash, and to allot 2,000 Ordinary shares (Nos. 1 to 2,000 inclusive) and 400 Preference shares (Nos. 220 to 619 inclusive) as fully paid.

AURORA ELECTRIC LIGHTING AND DISTRIBUTION COMPANY (LIMITED).—The second annual return of this Company, made up to October 12th, was recently filed. The nominal capital is £25,000, in £1 shares, and 5,935 have been taken up. 5,000 have been issued as fully paid, and the full amounts have been called and paid on the remaining 935 shares.

BERNSTEIN ELECTRIC LAMP COMPANY (LIMITED).—The annual return of this Company, made up to December 31, 1892, was filed on September 18, when 2,814 shares out of a nominal capital of £100,000, in shares of £10 each, were taken up and the full amount paid thereon.

SOUTH-WESTERN DISTRICT AND THAMES VALLEY ELECTRICITY SUPPLY COMPANY (LIMITED).—In connection with this concern no business has as yet been done. When the annual return was filed on October 18th last only the seven signatories' shares were taken up and the full amount paid in respect thereof.

WEST INDIAN DEVELOPMENT COMPANY (LIMITED).—This Company, which has for its objects the supply of electricity for the purpose of lighting the City of Bridgetown, in the Island of Barbadoes, has just entered into an agreement with J. Kenneth D. Mackenzie, of Broadway Chambers, Westminster, S.W., for the acquisition of a concession relating to the above, and in payment the Company has agreed to allot 4,000 shares, Nos. 71 to 4,070, both inclusive, to the vendor.

WEYBRIDGE ELECTRIC SUPPLY COMPANY (LIMITED).—When the 1893 return of this Company was filed 1,487 £5 shares were subscribed for and allotted. Of these 1,480 were issued as fully paid, and the full amount has been called and paid upon the seven signatories' shares.

CITY NOTES, &c.

BRIGHTON AND ROTTINGDEAN SEA-SHORE ELECTRIC TRAMROAD COMPANY.—The prospectus of this Company has just been privately issued. Out of 1,200 £10 shares the Directors have taken up £4,000 worth as Ordinary shareholders, and the promotors will receive 232 fully paid-up shares, leaving the remainder for private investors, but no public appeal for support is to be made. The railway is to run from Kemp Town to Rottingdean, and the Board of Trade have settled the terms of the licence for the ground to be occupied outside Brighton, and now have the general plans under consideration. When these are agreed to, the Brighton Corporation will be approached with regard to the site within their district. The line will comprise two pairs of rails 21ft. apart, to act as a single road, in order to permit of the car being as large and firm as possible. The cars, the dimensions of which will be about 18ft. by 30ft., will be to all intents and purposes a *fac-simile* of the saloon and upper deck of a steamer. It is said that the scheme has received very favourable comment from well-known engineers. The work will be put in hand shortly, and it is expected that the line will be completed by next Whitsuntide.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns for the week ending November 19, 1893 were £879, as against £899 for the corresponding period of last year, being a decrease of £20. The total receipts for the half-year amount to £16,425, as against £16,244 for the corresponding period, 1892, being an increase of £181.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—Notice is given in our advertisement columns that the coupons due December 1st, 1893, on this Company's issue of £100,000 Five per Cent. Registered Debentures (bonds Nos. 1 to 10,000) will be paid on and after that date at Messrs. Prescott, Dimsdale, Cave, Tugwell and Company (Limited), 50, Cornhill, or at the Royal Bank of Scotland, 120, Bishopsgate-street Within, E.C. Coupons must be left three clear days for examination. The register of debenture holders will be closed from the 24th to the 30th inst., both days inclusive.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ending November 17, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited) were £3,115.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ended November 15th were £2,237, as compared with £2,154 for the corresponding period of last year. The receipts for July, estimated at £3,658, realised £3,708.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 811.—Vol. XXXII. FRIDAY, DECEMBER 1, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

According to a statement made in the House of Commons by the Postmaster-General, on Monday last, the loss upon Press telegrams amounts to at least £300,000 a year. We call this a very handsome subsidy to the Press, and one for which it shows its lasting gratitude by an ever-increasing use of the wires. At this rate we may expect to see the cost of Press work swallowing up the receipts from all other sources. Mr. Picton seems to foresee this result, and to discount beforehand any ungenerous conclusions that might be drawn from it by people who do not sell newspapers. He asked Mr. A. Morley to say how much of the deficit was "received back by the public in the shape of cheap news." No answer was given to this abstruse question; and probably none was expected. What Mr. Picton wanted was to assert by implication that the public gets its moneysworth in cheap newspapers. The real truth is, rather, that newspaper proprietors are enabled to get valuable "copy" for next to nothing at the public expense. Reasons of State may justify this arrangement, but it is hard to see why the Telegraph Revenue should be made to pay for it.

That engineers of alternate current stations, in which the alternators cannot be run in parallel, should say, and perhaps think, that they do not want them to do so is only human nature. Those who can run their machines thus are proud of it. There is, however, a drawback to putting the whole plant of an alternate-current station on to 'bus bars. This drawback was felt at the Bankside station of the City of London Electric Light Company on Friday afternoon last week. The field circuit of one of the machines was accidentally opened or broken; the armature thus short-circuited the whole station. The fuse, which was arranged to prevent a 2,100-volt arc under ordinary circumstances, could not stand the strain, with the whole station behind it; an arc was formed, through which the other alternators sent their current; their fuses failed similarly, and for a few minutes the supply was stopped. This difficulty had been foreseen, and suitable cut-outs, similar to those used for charging batteries, were being made. The Thomson-Houston machines, at Wool Quay, amongst their other peculiarities, share a feature for which old-fashioned Brush machines were remarkable—they will stand short-circuiting. Dynamo makers do not all agree that this is worth the sacrifice of other features; but be that as it may, the Wool Quay machines went on with the supply, and no harm was done.

The municipalisation of electric supply is all very well where the ratepayers really wish to embark in industrial undertakings, and it is greatly appreciated by contractors and manufacturers of plant, since it opens a new market, possessing several attractions. But the summary rejection of the proposed electric light scheme by the Kensington Vestry on evening last week shows the unwisdom of attempting to push such ideas through without the support of the ratepayers. There is much preliminary fifing and drumming, advertising and discussing, but the moment the final step has to be taken the movement collapses. Though we are glad to see Local Authorities walking in paths already pioneered and made smooth for them by the enterprise and at the risk of private firms and companies, we have no sympathy with a Vestry that, by way of doing what private capital has left undone, seeks to interfere with existing works. The 13th Clause of the Provisional Order for which the Kensington Vestry was applying ran as follows:—

> To repeal, alter, or amend, if necessary, all or some of the provisions of the Kensington and Knightsbridge Electric Lighting Order, 1889, the South Kensington Electric Lighting Order, 1889, the Kensington, Knightsbridge and Chelsea Electric Lighting Act, 1893, the Notting Hill Electric Lighting Order, 1889, and the House-to-House Electric Light Supply Order, 1889, or any of them, and any other Act relating to or affecting the Vestry or the Undertakers under the above-mentioned Orders.

In some respects this may be as conventional as the suggestion that the Vestry shall construct their own plant and manufacture their own lamps, and that their officers shall be authorised to enter upon any houses or other premises supplied by them for any purpose relative to such supply. But if the Kensington Vestry, or any other local authority, attempts to poach on the property of existing companies they deserve to meet with a stout opposition.

If the system of compulsory areas and permissive areas is not found to answer it had better be altered. The Provisional Order of the Kensington Vestry was not confined to working in permissive areas which had not been covered by existing companies, but it contemplated, in Clause 3, actual competition in streets at present supplied. Competition by a vestry simply means confiscation. Clause 4 of the Order gave a list of streets in which it was proposed to lay mains within a specified time. These streets were all in the Ladbroke-grove neighbourhood, to the north and to the west of the Notting Hill Company's district. This is the second area of the

Digitized by Google

House-to-House Company, and one which they have never touched. No objection could have been taken to this, since five years have elapsed since the Company applied for it.

THE letter from Messrs. HAYCRAFT and GAWTHORP, which will be found in our correspondence columns, raises several points of theoretical interest in connection with gas testing, but in the absence of any actual observations, we are inclined to adhere to our opinion as to the importance of corrections for temperature and pressure. It was pointed out by Mr. FRANK WRIGHT, at a meeting of the Physical Society on June 9, 1893, that since about ten volumes of air are consumed by a gas burner for one of gas, the temperature of the air is of considerable importance. Mr. METHVEN, in a Paper read in 1889 before the South-Western Association of Gas Managers, showed the great effect of aqueous vapour in the air on the candle-power of gas burners. The surrounding air, from one point of view, may be said to be the fuel, and the gas only the wick of the flame. We understand that an expert gas tester, if he has time, and the inclination, can dodge a 16-candle gas flame to give 19 candles, or more. A good deal of the secret depends on temperature.

THE standard candle is not, we believe, affected in the same way as a gas-flame by conditions of temperature, pressure, and aqueous vapour, but no complete experiments seem to have been made on this point. The candle-power of a gas flame obviously depends upon two main factors, the size of the flame and its intrinsic brilliance. If changes of temperature and pressure affect these two factors differently, as is probable, an open gas flame tested against a Methven standard will by no means maintain a constant ratio, as suggested by our correspondents. Their argument that the temperature of the flame is high, tends to show that the intrinsic brilliance would, perhaps, not be greatly altered.

THE allusion to wave-motors in the Articles on "Motive Power and Gearing," commenced in our present issue, may seem rather far-fetched, but it helps to make the list complete. We understand, however, that experiments are being seriously carried out by Mr. SCOTT SNELL in this direction. Such a motor has been tried for pumping, and the late Mr. FROUDE believed that under some conditions the device would be feasible. It would not be so regular as a tide mill, and does not appear to present advantages over the ordinary forms of windmill. It is the first cost and maintenance of such motors that settles their value. They enjoy the privilege, common to but few engines, of being destitute of any efficiency in the strict sense of the term.

OUR American contemporary, the *Electrical World*, recently propounded the following riddle, the solution of which it leaves an open question. Suppose that an annular vessel, filled with some electrolyte, were placed inside a solenoid carrying an alternating current; and suppose that the conditions were so adjusted as to give an induced electromotive force in the electrolyte sufficient under ordinary circumstances to produce electrolysis. Would there, our contemporary asks, be any electrolytic decomposition produced? The problem is a curious one; but surely there can be little difficulty in seeing that there would both *be* and *not be* electrolysis. For would not the positive ions march round the annular liquid in phase with the induced current, in a complete chain or circle; and the negative ions in anti-phase, in the same circle but in the reverse direction? The atomic interchanges would go on, but no free ions would be liberated

SINCE $\frac{A \times d \times p \times d \times \sqrt{d}}{p \times A} \times (\cdot 0184\, \alpha\, \beta\, \delta\, v \times 1140) \sqrt{\frac{w\, k)\, \eta}{\epsilon}})$ $= d^2 \sqrt{d} \times (21 \times \alpha \times \beta \times \delta \times v \sqrt{\frac{w \times (k) \times \eta}{\epsilon}}$, and a few other very obvious considerations, Mr. A. E. WIENER shows, in the *Electrical World*, of New York, that the output of dynamos increases as the 2·5 power of their linear dimensions. Is this engineering, is it science, or is it only mixed mathematics? We learn that "this exponent is a very important constant for practical dynamo calculation." When somebody has built one dynamo to his satisfaction, and, to take a pleasant case, has sold it, and has received a repeat order for another of three times the output, is he to proceed to build it, using the old design to another scale? If not, what is the use of two long columns of mathematics? On the other hand, if somebody is inquisitive enough to investigate the relation between dimensions and output, why not take the price lists of one or two good makers, and plot a curve of weights and output? It will be found that this is practically a straight line, tending towards a small constant weight, say 1cwt. to 3cwt., and rising at the rate of 1cwt. to 1½cwt. per kilowatt, more or less, depending on the type and speed of the machine. But a 100 kilo-watt dynamo of the same pattern as a one kilo-watt machine is probably a bad one, if the latter is a good one.

Personal.—We are informed that *Industries and Iron* has lost the services of Mr. James Swinburne as Electrical Editor, but that he will remain a contributor to that journal.

Bleaching by Electric Discharge.—In a Silesian establishment for bleaching linen yarns electric discharges are used to generate ozone. This gas acts on the yarns suspended in chambers.

Obituary.—Mr. James Brand, whose death is just announced was formerly Chairman of the Board of the United Telephone Company, chief of the original undertakings now merged in the National Telephone Company.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	October 25th.
Cayenne-Vizeu	November 25th.
Jamaica-Colon	November 25th.
Bissao-Bolamo	November 24th.

Coast Communication.—Telephone communication has now been completed between the Gunfleet lighthouse and the coast guard stations at Harwich, Walton-on-the-Naze, and Clacton-on-Sea. It will be of invaluable service, as by it a message can be sent by voice from the Gunfleet to the stations named, apprising the lifeboats when ships strike on the treacherous sand with which the lighthouse is surrounded.

Test of Gas Burners.—Our attention has been called to a Report by Capt. Webber (now Major-Gen. Webber) and Mr. Rowden, on "Apparatus for Ventilating, Warming, Cooking and Lighting, in connection with the Paris Exhibition of 1867." Tests of many gas burners are given, but 26 years have elapsed

Digitized by Google

since they were made, and as Paris gas was used they have lost somewhat in practical interest. The Report is very elaborate, and contains much interesting matter.

Utilisation of Water Power.—A company has been organised to build a wing dam on the Delaware river near Trenton, U.S.A., which will be equipped with a complete outfit of sluice ways and turbines for the generation of power. The works will be located at Morrisville, and the power will be sold to Trenton shops and factories. The Company is empowered, amongst other things, to erect and lay cables and wires overhead, under water, and underground for the transmission of electricity.

Electricity on American Canals.—The Alabama and Georgia Canal and Transportation Company has, says *Industries*, been formed, with a capital of $5,000,000, to build 150 miles of canal between Decatur, Birmingham, and other Alabama towns, with extensions later to Columbus, Savannah, and other towns in Georgia. The propelling power will be a stern screw, which will be operated by electricity. In order to do this the trolley system will be used along the portions where the canal is used. The canals will be the usual width, which will admit of two wires being strung, making a kind of double-track system.

The Moissan Electric Furnace.—In the *Comptes Rendus* for November 20th, M. Henri Moissan describes the latest type of electric furnace employed by him. His first furnace consisted of two hollow blocks of quicklime, which were super-imposed one on the other. In the type of furnace now described by him he has substituted blocks of Coursom stone for the quicklime briquettes, and has lined the interior with four layers of magnesia and carbon, arranged alternately, the first layer of magnesia being next to the arc. By the employment of magnesia higher temperatures can be attained than has hitherto been the case.

Lamp Statistics.—We are all familiar with the singular way an astronomer has of conveying an idea of big numbers. He tells us, for instance, that if a baby had an arm long enough to touch the sun, the baby would be 21 years old before it would feel any pain in its finger. Someone has been putting the statistics of the United States glow-lamp manufacture into a similar form; and he tells us, in an American contemporary, that since the output of one factory is one million lamps per annum there will be five million lamps made, at this rate, in five years, and that if all these lamps are put end to end they will extend along a line 39,457 miles long.

Preservation of Timber by Electrolysis.—The impregnation of timber can, it is said, be very quickly and expeditiously carried out by the aid of electricity. The apparatus comprises, says the *Moniteur Industriel*, two boilers for the preservative liquid to be injected, a circulating pump and its motor, a steam boiler and a dynamo. The saline liquid is heated in the usual manner by means of a current of steam. At the same time an electric current is passed through the impregnating boiler. The combined action of the electric current and the heat causes the timber to be thoroughly impregnated in one hour, while the usual process with heat, but without the electric current, takes from 10 to 40 hours.

Proposed Electric Tramway for Cork City.—Steps are now being taken to introduce electric trams into Cork City. The Privy Council have notified the Cork Corporation that the judicial Committee will sit at Dublin to-day to hear the application for the erection of electric tramways in Cork. A memorandum has also been sent from the Privy Council to the Corporation, in which the Inspector (Major Hutchinson) points out the various objections to the scheme as disclosed in the plans, particularly as regards narrow streets. The Corporation have decided to supply information to the Privy Council on the points raised, and to intimate that the Corporation are willing to fall in with the views of the Board of Trade on the matter in every respect.

Plymouth.—As will be seen by our list of Electric Lighting Notices this week, there promises to be a somewhat amusing competition down Plymouth way. The Corporation have gone in for a Bill to give them the power to supply the electric light in the chief business streets. No sooner had they given in their notices than the Plymouth Gas Company goes in for the same sort of thing, the only difference being that while the Corporation evidently hope to use the water-power of their water system to supply the necessary power, the Gas Company intend to use their gas. It seems a pity that, in view of the well-known *penchant* of Parliament for municipal electric lighting, there is not much chance of this interesting battle ever coming off.

Electric Lighting and Dowson Gas at Cleator Moor.—Last week the Cleator Moor Co-operative Society celebrated the opening of the Society's new flour mill, warehouse, and bakery. The Society formerly possessed a mill and warehouse, which were burnt almost to the ground in July, 1892. This was fully covered by insurance, and with the money received from the insurance companies the Society has been enabled to re-erect the mill and warehouse, substituting more modern machinery and appliances. The mill machinery is driven by two gas engines of 200 aggregate I.H.P. The engines are supplied with Dowson gas. The Society have, further, gone in for lighting by electricity. At present there are about 70 16-candle glow lamps lighting the mill and the warehouse.

The Art of Passing Examinations.—The current number of *The Sphinx*, the University College (Liverpool) Students' magazine, contains a sensible article on this subject from the pen of Dr. Oliver Lodge, who, many-sided as he is, evidently does not appreciate the delights of acting as examiner:—"When an examinee," says Dr. Lodge, "I regarded an examination with a feeling of pleasant exhilaration; as an examiner I loathe its dismal sequel with unmitigated disgust. Little enough time does one find to read the great writings of the masters of one's subject, but to read through piles of manuscript of the feeblest (sometimes of the most idiotic) description, and to keep one's mind on the strain to appraise ever particle of value which can be detected amid the refuse, is an occupation unfit for a scavenger."

Old Students' Association.—The Committee of the Old Students' Association, in presenting the annual report and statement of accounts for the eighth session (1892-93), remark that, "in order to attain a still larger measure of success, the Association should be so developed that its operations do not conflict with those of other bodies. There are equally successful societies for the purpose of reading scientific Papers, and it therefore seems to us that, in the future, greater prominence should be given to the social aspects of our work, a department which has always formed the strongest bond of union between our members." For this reason the Committee have deferred the election of the new officers till such time as they could submit to a general meeting suggestions for the future working of the Association.

Bristol.—There was a meeting of the Electrical Committee of the Corporation last week, when various matters relating to the electric lighting scheme were considered. It was thought that the lighting in Victoria-street and Bristol Bridge had proved successful. The Committee decided to increase the plant by purchasing another engine, and a second additional engine will probably be required before many weeks. The demand for incandescent lighting continues to increase in the most encouraging manner. The Finance Committee of the Town Council have decided that they will not at present light some of the municipal offices by electricity, and that will place something like 2,000 incandescent lamps at the disposal of the Electrical Committee to meet other requirements. The total number of incandescent lamps for which orders have been received is 14,000, or 4,000 beyond the limit of supply contemplated when the present plant was arranged for, and the Committee are commencing with 90 per cent. of their power utilised.

Kensington Vestry Electric Lighting Scheme.—A special meeting was held last week to consider the question of electric lighting to be undertaken by this Vestry. Mr. Ellis ridiculed the whole report, and said the attempt at electric lighting in St. Pancras was a complete fiasco. A more madcap scheme had never been set before the public. He moved the rejection of the report. Mr. Robinson pointed out that not one in four residents in the Lansdowne-road had asked for the electric light. Mr. Blanckensee having spoken against the report, the

Digitized by Google

amendment to reject it was put and carried by nearly three votes to one. The following proposal of the Notting Hill Electric Lighting Company was then rejected on the recommendation of the Electric Lighting Committee. The Company's proposal with regard to area "B" was that the Vestry should co-operate with the Company to enable it to obtain the said area, without however putting on it any obligation to wire streets which might appear to be unremunerative, and that the Vestry should have the right of laying down mains in any street or streets which the Company were unwilling to wire, starting from any of their "feeder-points," the Company undertaking to supply the current to such mains at half the cost they were at present authorised to charge, the Vestry to make their own terms with private consumers.

The Official Vocabulary for Code Telegrams.—This vocabulary is now being prepared by the International Bureau of Telegraphic Administrations at Berne, in accordance with the decision of the International Telegraphic Conference of Paris, 1890. It will contain about 240,000 words, selected from the eight authorised languages—English, French, German, Spanish, Italian, Dutch, Portuguese, and Latin. Inflections of words, declension, conjugation, comparative and superlative, will be used, as well as a certain number of proper names. The words will contain at least five and at most ten letters, and will form a single series, alphabetically arranged, and numbered from 000000 to 240,000, the different languages being mingled according to alphabetical order. The words are not to present any distinction showing the language to which they belong, and each page will measure 11·8in. by 7·87in., containing 300 words. The vocabulary is to be printed in clear characters on paper of good quality. Editions containing part of the words, or the words of a single language, will not be published. Three years after publication the use of this official vocabulary will become obligatory for the European Telegraphic Service, and later on, doubtless, for extra-European messages. The vocabulary is the property of the administrations forming the Telegraphic Union, who will bear in the first instance the cost of compilation and printing. It is announced that the official vocabulary will be published some time in 1894.

High-Frequency Currents. — In a recent issue of the *Electrical World*, of New York, Lieut. Patten, following in the footsteps of Mr. Trouton, shows how high-frequency currents may be practically generated by a series of similar alternators with their armatures on the same shaft, and the field of each excited by the current from the armature next before it in the series. As pointed out, however, the electromotive force, if the alternators are identical, is decreased in the same ratio as the frequencies are increased, which limits this disposition for practical purposes. The device might have been useful for the production of very high-frequency currents for theoretical purposes, if it had turned out that the frequency was doubled by each additional armature, as in that case only a few armatures would have been needed to produce very rapid alternations. But, unfortunately, the frequency is simply increased by a constant amount with each successive armature, and the chief value of the method for experimental purposes is found in cases where it is desirable to know the exact frequency. It should be borne in mind, says our contemporary, that, apart from the usual losses in the different fields, armatures, and condensers, there is no loss of energy due to the successive decreases in output. This decrease follows from the character of the field generated by the alternating field current, which reduces the output of the armature, but yet only expends energy in proportion to the reduced capacity.

The Tower Platform for Naval Search Lights.—An important series of experiments in gunnery and kindred subjects has recently been completed at Silloth, on the range belonging to Sir William Armstrong, Mitchell and Co., in the presence of a large number of representatives of several European Powers, of the United States, and of Japan, for the purpose of Exhibiting the latest results which have been obtained at elswick in the improvement of artillery. Amongst other things a new form of naval search-light was exhibited, on the ingenious platform invented by Mr. Beauchamp Tower. This contrivance is of great interest, as it obviated the unsteadiness and uncertain direction of the light ordinarily produced by the rolling of any vessel carrying it. The details of the mechanism have been published in a Paper read some years ago by the inventor. A platform rests upon pistons working in hydraulic cylinders, and a jet of water is directed by a gyroscope into one or more of these cylinders, the jet being in the direction of the axis of the gyroscope. The apparatus was placed on board a small vessel, and a beam of light was directed upon an object in the water. The vessel was then caused to roll violently; but, in spite of the rolling, the beam remained directed upon the object as steadily as if the light had been upon the jetty. The apparatus was then thrown out of gear, so that the search-light became an ordinary fitting; and it was then shown to be useless while the boat was rolling, it being no longer possible to keep the beam directed upon the object even for a moment.

Press Telegrams and the Telegraph Revenue.—In the House of Commons on Monday evening Mr. Picton asked the Postmaster-General whether he had now obtained the information which he was unable to give on June 19th, as to the pecuniary results to the Post Office of the difference in the charges made for Press telegrams as compared with ordinary telegrams; and whether he could say approximately how much of the deficit in the telegraph service was received back by the public in the form of cheap news. Mr. A. Morley said that he found that the cost of an examination of the messages for any lengthened period would be so great as to be prohibitive, and he therefore directed that the calculations should be limited to a particular day. The result was to show that if the Press messages of that day had been paid for at the ordinary inland rate the Department would have received nearly eight times as much as it actually did receive. For the reasons which he gave on June 19th it was impossible for him to separate the cost of dealing with Press telegrams from that of the rest of the Telegraph Service, and he could not therefore state what was the loss incurred by the Department. When the account of the gross amount received and expended on account of the telegraph service for the year ended March last is presented to Parliament it will be found that, apart from the interest on capital, the balance of expenditure over receipts was about £150,000, and the best estimate that could be formed by the officials at the Post Office pointed to the annual loss on Press telegrams being at least double that amount, and probably a still larger sum. He believed the test day selected was July 8th.

The "St. Martin's-le-Grand Magazine."—The occasion of the annual dinner of the *St. Martin's-le-Grand*, the Post-Office magazine, was seized upon as an opportunity to welcome Mr. Spencer Walpole on his appointment as secretary to the General Post Office, and also to gather together a large number of past and present officials of the service. About 260 gentlemen assembled at the Freemasons' Tavern on Tuesday night, among them being the Postmaster-General, Mr. Frank Lockwood, Q.C., M.P., Mr. W. H. Preece, and Messrs. H. Joyce, J. C. Lamb, H. C. Fischer, &c., &c. Mr. W. H. Preece proposed the health of the Postmaster-General. The Postmaster-General, in replying, said he must attribute the cordiality of their reception to the office which he had the honour to hold. The toast had been originally intended for proposal by their guest, Mr. Lockwood; and as it occurred to his mind that his hon. friend was interested in an extension of the telegraphic service, which had not been carried out because the vote of money for the purpose did not permit, he had prepared himself to meet an exposure of the faultiness of the Post Office as a department, and the shortcomings of the Postmaster-General who now unworthily occupied that position. Fortunately they were spared the flow of reminiscence and remark which he had provided himself with against that contingency. He was glad to see they had seized the earliest opportunity of making the acquaintance of the new secretary, who, he was sure, would perform his duties in a manner to hand down to posterity the highest traditions of his predecessors. Postmasters-General came and went, and their official connection with the department was generally under three years. Mr. Lockwood and Mr. Spencer Walpole also spoke.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

Motive Power.—The study of motive power leads us to consider those arrangements of mechanical parts, which are most conveniently called *engines*, in which the energy of some natural source is either directly or through a chain of processes transformed into the energy of mechanical motion. The term engine will, therefore, include in its widest sense all the machinery between the actual natural source or supply of energy, such as the coal in a boiler furnace, and the contrivance in which the required form of mechanical motion takes place. It will, however, be found more convenient to limit the meaning of the term, and to divide the train of mechanical parts under three classes: 1st, the preparatory parts, such as the furnace and boiler in a steam-engine plant, or the races in a water mill; 2nd, the engine proper, in which the energy in a suitably prepared form is finally converted into mechanical motion of machinery; and 3rd, the gearing, in which this mechanical motion is modified to suit the special requirements of the dynamo. Motive power is at once seen to be necessary in electrical engineering, because it is impracticable to derive electrical energy, as such, from any natural source so that it can be conveniently used. The dynamo is the most common mode of deriving electrical energy from suitable prepared mechanical energy.

The need for the third stage in the series of energy transformations arises from the fact that it is often necessary to place the dynamo in connection with an engine running at an unsuitable speed, or to have the engine and dynamo at a considerable distance apart.

It will be convenient to include under the term *gearing* all mechanical parts, whether moving or fixed, which are interposed between the engine proper and the dynamo, and which aid the transfer of mechanical motion from the former to the latter. There is a distinctly different application of gearing in the case where an electric motor is adapted to run any machine through the intermediate action of a train of mechanism, all such mechanism being here also called gearing.

Energy. — There are only two things in the material universe—energy and matter, or—some would say energy and ether—making ether and matter one. Energy, however, is not strictly regarded as a *thing*, that is to say, as having separate existence in itself. Energy is a condition or set of conditions in matter; it is that condition in matter which enables the matter to exert force against any resisting force, and to overcome that resistance through a distance. Energy, then, is that which enables a body to push backwards against a force through a distance along its line of action. Now, when a force is exerted it must be exerted against another force, equally great, arising from the external or internal resistance of the body against which the force is exerted. The measure of the energy exerted is equal to the product of the acting force into the distance along its line of action through which it overcomes the resistance. The product of the resisting force into the distance through which it is overcome is called the *work* done on the resistance.

Work, Power, and Velocity.—It follows, then, that in all cases of the mutual action between two or more bodies, the energy exerted will be equal to the work done, or the energy expended by the acting force will be equal to the work done against the total resistance. So, then, energy is the capacity for doing work. It can be shown that every body which exerts force through any distance along its line of action and in its direction, must expend energy. It is equally capable of proof that every body which opposes a resisting force which is overcome along its line of action must absorb—and retain or dissipate—an amount of energy equal to the amount expended by the acting body. Whence it follows that in none of the mutual actions between bodies is any energy lost, neither is any energy created. This theorem is called the doctrine of the conservation of energy. Work is the transference of energy from one portion of matter to another, and the measure of the work is the measure of the amount of energy lost by one and absorbed (to be retained or dissipated) by the other. The rate at which this transference is taking place at any instant is called the *power*; or the average power is the ratio of the amount of energy transferred to the time taken to transfer it.

Power, in other words, is the rate of working, it is sometimes called the *activity*. If a force, F, is exerted through a distance, L, in a time, T, the amount of energy expended by the body exerting the force, F, is equal to F multiplied by L, and the power is equal to this quantity divided by T, or is equal to the product of the force, F, into the ratio of the distance, L, to the time, T. But this ratio is equal to the velocity of the point of action of the force, F, along its line of action; or, if the velocity is not constant, this ratio is the average velocity and gives the average power. If, however, the velocity is constant during the time, T, this will give the actual power at any instant in that time. Whence, the power at any instant is equal to the product of the force acting at that instant into the velocity with which its point of application is advancing along its line of action at that same instant. Or generally, power is the product of force into velocity.

There are two general kinds of velocity involved in the question of power: linear velocity and angular velocity, or speed. Linear velocity is the rate of motion of any body or point along a line, whether curved or straight; it is expressed in units of length traversed in unit time, assuming the rate to remain unchanged during the unit time. Angular velocity is the rate at which any radius sweeps through an angle, as in the case of a radius of a rotating wheel. If any radius is chalked on a flywheel or pulley, and the wheel is turned round, it will be found that the radius has passed through an angle at the centre of the wheel, the angle being made by the positive inclination of the new position of the chalk line to the old position. If this angle is divided by the time taken to pass through it, the average angular velocity of the radius has been determined. In one revolution, an angle of 2π radians or 360deg. has been passed through. We may express angular velocity as the number of radians, or degrees, or revolutions swept through by any radius in unit time, such as a second or a minute. Speed is usually expressed in revolutions per minute. Let N be the number of revolutions per minute; then the number of radians swept through in a minute will be $2\pi N$, and the angular velocity, ω, in radians per second will be

$$\omega = \frac{2\pi N}{60} = \frac{\pi N}{30}. \quad . \quad . \quad . \quad . \quad . \quad (1)$$

In motive power angular velocity almost exclusively belongs to motion in a circle, in which, of course, there is a constant radius. Let r be the radius of motion. The linear velocity round the circle will be, in units of length per second,

$$v = \frac{2\pi r N}{60} = \frac{\pi r N}{30}. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Substituting the value of N, obtained from this last equation, in the one preceding it we get—

$$v = \omega \times r. \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

The above shows that, in circular motion, the angular velocity is the ratio of the linear velocity to the radius of the line. Where power is to be transmitted by angular motion it is often more convenient to express it in terms of angular rather than of linear velocity. This may be done by expressing linear velocity in terms of speed. Thus

$$\text{Power} = P = F.v = F.\omega.r. \quad . \quad . \quad . \quad . \quad (4)$$

The product $F.r$ is called the moment of the force, whether acting or resisting; it is also called the torque, and is represented by the symbol τ; whence the power in units of work per second is equal to—

$$P = \tau.\omega, \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Units.—In mechanical engineering the system of units adopted is based upon different fundamental units to that adopted in electrical engineering. The mechanical

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights reserved.

Digitized by Google

or gravitation system is derived from the *foot* as the unit of length, the *second* as the unit of time, and the weight of a standard *pound* at Greenwich sea level as the unit of force. From these are derived the following units:—The foot-pound, as the unit of energy and work, being the work done by a force of one pound acting through one foot. The foot-pound per second is one unit of power; but a more common unit is the horse-power, invented by James Watt, which is equivalent to 550 foot-pounds per second, or 33,000 per minute. Velocity is expressed in feet per second; angular velocity in radians per second, or revolutions per minute; and torque as the product of a force in pounds into a radius in feet, usually called pounds-feet to distinguish it from foot-pounds. It is sometimes convenient to express a torque in inch-pounds, where the radius is expressed in inches. The unit of mass in this system is designed to correspond to the units of force and velocity, and is such that if a force of one pound acts on it for one second it will acquire a velocity of one foot per second. Inasmuch as the weight-force of a pound acting on its own mass alone will cause it to acquire a speed of 32·2ft. per second at the end of one second (g), it will be evident that the unit of mass must be 32·2 times more massive than one pound, or will equal 32·2lb. Electrical engineering units are based upon the *gramme* as the unit of mass, the *centimetre* as the unit of length, and the second as the unit of time. From these are derived the *dyne* as the unit of force, the *erg*, or dyne-centimetre, as one unit of work, the *joule*, or 10^7 ergs, as a higher unit of work or energy, and the Board of Trade unit as the commercial unit of work or energy. This last is based upon the *watt*, or unit of power (which watt is equal to one joule per second), and is equivalent to the work done by a power of 1,000 watts lasting for one hour. A kilowatt is equal to 1,000 watts, so that a B.T. unit (Board of Trade unit) is equal to one kilowatt-hour. A simple calculation will show that one horse-power (H.P.) is equal to 746 watts, and that one B.T. unit is approximately equal to $1\frac{1}{3}$ H.P.-hour.

Sources of Energy.—Energy, which as we have seen is indestructible, is capable of numerous transformations. The forms under which it exists in nature and in engineering are many and varied. Yet they may all be classed under two heads; and these two under one great head, energy. In other words, any energy in one class may be so modified that it must be transferred to the other class. There are not two isolated quantities of energy. The two great classes are: energy of motion and energy of stress; or kinetic and potential energy, as they are respectively called. Kinetic energy is the energy which a body possesses by virtue of its motion, and which enables it to do work against a retarding force, as for example the energy of a cannon ball or of a fly-wheel. Potential energy is the energy which anybody possesses by virtue of the stress and strain to which it is subjected by the proximity of some other body. Thus, a raised weight possesses energy even when at rest, because of the proximity of the attracting earth. To be quite exact this form of energy belongs to the medium of the stress and not directly to the bodies between which the stress arises; but because it is possible for either or both of these bodies to acquire this energy at any time, by a relative change of position, this is called their *potential* energy. All the forms of energy with which we are acquainted come under one or the other of these two heads. The immediate sources of energy in nature are numerous, though it is possible to trace the greater number of them to solar heat. The principal forms of energy are as follows:—

Kinetic Energy.	*Potential Energy.*
Moving bodies.	Raised weights.
Sound waves.	Sound waves.
Light (Radiation).	Light (Radiation).
Heat.	Electric stress.
Electric current.	Magnetic field.
	Chemical stress (Fuel).
	Elasticity.

In the case of waves, both forms of energy are alternatingly assumed; while many of the forms of energy have been repeated in the same column for the sake of clearness. Thus the potential energy of waves is due to elasticity, and the kinetic energy of sound waves is due to moving particles. Motive power for machinery is, however, derived from a more limited number of sources than those mentioned, namely, from (1) fuels; (2) water raised to a height by solar heat; (3) the tides; (4) wind power, including wave power, and (5) muscular power. These are dealt with in engines of the following description:—

Fuels	Heat Engines	Steam engines. Hot-air engines. Gas engines. Oil engines.
Water Power	Water Motors	Water wheels. Turbines. Hydraulic motors.
Wind Power		Wind mills. Wave engines.

Machinery for developing useful work by muscular power has not received much attention, except in the case of locomotion, and does not call for any consideration here.

(To be continued.)

TESTS OF GAS BURNERS.

(Concluded from page 96.)

Wenham Gas Burner (burner over lecture table in Room 32). Candle-powers were taken by aid of the mirror. Consumption of gas due to by-pass was found to be 2·07 cubic feet per hour when the flame was turned as low as it could be turned in practice. The average consumption in these burners is probably nearer 2·5 cubic feet per hour.

The candle-power of the Wenham light increases, of course, with the temperature of the regenerative arrangement. It was found impossible to get constant readings for more than half an hour after lighting. Some of the time readings are as follows, the consumption remaining practically constant:—

Candle-power.	Time.	Candle-power.	Time.
55·8	0	100·5	20 min.
67·7	5 min.	100·6	30 „
91·0	10 „	112·0	40 „

The candle-power thus actually doubles in 40 minutes.

Tests of the Governor.

Pressure.	Cub. ft. per hr.	Pressure.	Cub. ft. per hr.
2·5	14·02	0·47	9·57
1·5	14·30	0·4	7·53
0·5	12·35		

The governor thus acts very well over a considerable range, and the candle-power will not vary much as long as the pressure exceeds half an inch. The candle-power having reached its maximum at the end of about 40 minutes the light given in various directions was obtained by aid of the mirror, the photometer bench being placed in various positions in the room. The result of these measurements will be given in a section on spherical candle-power.

It is noticeable that the consumption of gas actually decreases as the pressure increases above half an inch, the governor acting rather too readily. The rise of pressure from 0·55 to 1·2 occurred suddenly somewhere about a quarter to six, and was due to a rise of pressure in the mains.

Time did not permit of a number of observations of relation between candle-power and consumption being taken, as 45 minutes would have to be allowed each time for the burner to reach a constant temperature. These burners are, however, almost invariably turned full on when in use, and such observations would have no practical value.

Albo-Carbon Burner.

The type tested was that in which the albo-carbon reservoir is immediately below the burner, which was found to subtend a solid angle $2\pi \times 0·057$, thus cutting off 2·8 per cent. of the

Digitized by Google

light. The weight of albo-carbon consumed in a known time was taken, this being an important item in the expense :—

C.P.	Cubic feet per hour.	Pressure.	Efficiency.	
28·6	5·62	1·5	5·09	Face.
25·8	—	—	4·59	Edge.

Weight of albo-carbon consumed in 90min. = 14·48 grams = 9·65 per hour. Cost of albo-carbon at 2d. per pound = 0·0441d. per hour.

C.P.	Cubic feet per hour.	Pressure.	Efficiency.
20·0	3·85	0·85	5·2

Weight of albo-carbon consumed in 197min. = 26·93 grams = 8·19 grams per hour. Cost of albo-carbon at 2d. per pound = 0·0374d. per hour.

London Argand (Sugg's) Burner, No. 1.

Distance from photometer.	C.P.	Cub. ft. per hour.	Pressure.	Efficiency.	Height of flame.
113·3	19·1	5·90	1·3	3·22	3"
110	15·1	5·2	1·05	2·91	2·1"
106·2	11·8	4·55	0·85	2·59	1·7"
91·2	4·81	3·48	0·45	1·38	1·0"
63·5	1·08	2·4	0·35	0·456	0·6"

The efficiency of the burner increases with the consumption of gas, and at 20-c.p. is higher than is obtained with any other burner except the albo-carbon, Welsbach, and large candle-power burners.

Welsbach Incandescent Burner, No. 2. (New Mantle.)

D.	C.P.	Cub. ft. per hr.	Pressure.	Efficiency.
105·4	11·1	1·4	0·2	7·93
114·3	20·5	2·05	0·55	10·0
115·5	22·4	3·15	1·45	7·12
115·7	22·7	3·15	1·7	7·22

This is by far the most efficient burner tested,* the efficiency being 10 candle-power per cubic foot at 55min. pressure.

Spherical Candle-power of Gas Burners.

Measurements of candle-power in different directions were made with the mirror.

Bray's No. 5 special Batswing was measured in 12 different directions, taken nearly uniformly over a sphere. The mean spherical candle-power was found to be almost exactly that of the edge of the flame in the horizontal plane, or about 92 per cent. of the horizontal candle-power full face. Bray's enamel regulator No. 5, and other fish-tail burners, gave a mean spherical candle-power practically equal to the horizontal candle-power, which is nearly uniform all round.

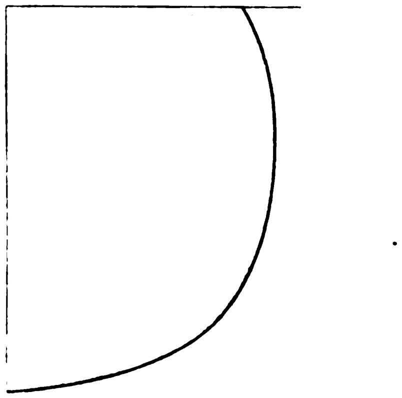

Fig. 6.—Spherical Candle-Power of Wenham Burner.

Wenham Burner.—Large variations of candle-power at different inclinations to the vertical were found.

Angle with vertical	C.P.	Angle with vertical	C.P.
0	110·0	60°	90·3
35°	109·7	80°	76·6

Mean candle-power below the horizontal plane (found) from area of curve = 95·1. Mean spherical candle-power = 47·5.

* Renewals of mantles and glasses, very considerable items, appear to have been omitted.—Ed. *E.*

This gives the mean efficiency as 3·3 candle hours per cubic foot.

London Argand Burner.—The flame being symmetrical about a vertical axis, measurements in only one vertical plane were taken. d_1 and d_2 refer to distances explained in Fig. 2, page 94 of our last issue :—

Angle. deg.	d_1	d_2	Cub. ft. per hr.	Apparent C.P.	Real C.P.
−80	24·5	57·5	6·3	1·88	2·29
−70	28·0	74·3	—	4·57	5·57
−45	36·0	93·5	—	14·2	17·3
0	28·5	99·3	6·3	17·8	21·7
45	33·0	98·6	6·35	18·4	22·5
66	31·0	98·4	—	16·8	20·5

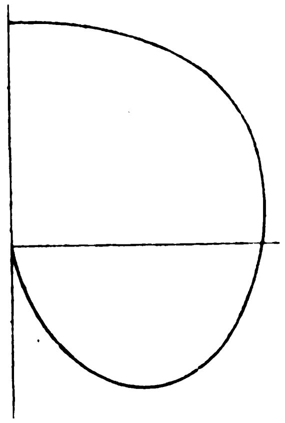

Fig. 7.—Spherical Candle-Power of London Argand Burner.

The value of the spherical candle-power obtained from the curve is 15·1 apparent or 18·4 real. Horizontal C.P. = 21·7, mean spherical = 18·4, or 15 per cent. less.

Spherical C.P. of a Standard Candle.

Angle deg.	d_1	d_2	Apparent C.P.	Real C.P.
−75	24·0	26·8	0·34	0·414
−68	26·0	37·6	0·64	0·78
−60	27·0	40·7	0·76	0·926
−52	35·5	35·5	0·77	0·939
−30	24·7	43·7	0·82	1·00
0	21·5	46·7	0·87	1·06
+15	19·5	49·9	0·96	1·17
45	26·0	44·3	0·89	1·09
60	23·0	48·2	0·98	1·19
69	22·0	46·7	0·88	1·07

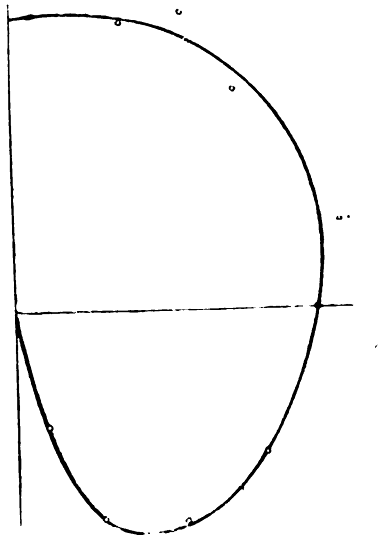

Fig. 8.—Spherical Candle-Power of a Standard Candle.

The curve gives:—Mean spherical C.P. (real) = 0·94, horizontal C.P. = 1·06. The mean spherical C.P. is, therefore, less than the horizontal C.P. by 11 per cent.

We propose to consider some of the results given in this report in a future article, comparing the cost of gas lighting by different burners with the cost of electric lighting by glow lamps.

CARBONS FOR ELECTRICAL USE.

Abundant evidence exists that such knowledge as has been gained of the principles on which the manufacture of carbons for electrical purposes rests, and of the adjustment of quality to the use to which the carbons are to be put, is scarcely adequate for present industrial requirements. The absence of precise information on many essential points has lately been publicly demonstrated in a case ("Thompson *v.* Cowles") recently reported in these pages. It will be remembered that the question then at issue was whether carbons supplied for the production of aluminium by electrolysis were suited for this purpose, and that, taking the evidence as given without comment, it appeared that carbons which one firm had chosen after extensive practical trials were rejected by another on the ground that they were not fitted for the same work. In view of this direct conflict of experience it is plain that the selection of carbons for a given purpose is more than tinged with uncertainty, and it is reasonable to inquire concerning the chief reasons for this dubiety and the methods by which it may be diminished or removed.

The "carbon points" used by Davy for exhibiting the electric arc were merely sticks of wood charcoal. Retort carbon was soon afterwards used, on account of its hardness and slower rate of consumption; and square rods sawn out of gas retort carbon were in use by several makers of arc lamps at the Paris Electrical Exhibition of 1881. But even at that time very fair arc carbons were manufactured, and gradual improvements have been made since then, until a few brands exist which are nearly perfect under the conditions for which they are intended. Until the use of electrical furnaces, electrolytic or otherwise, had passed the experimental stage, bundles of ordinary arc carbons were used, as in the Siemens furnace shown at a Kensington exhibition some years ago, and on the appearance of a demand, carbon makers began to turn out large carbons made with but trifling modifications of their ordinary process.

As is almost invariably the case in manufactures that have had to be undertaken to meet pressing commercial demands, the practice of carbon-making has far outstripped the knowledge of the principles that should guide the practice, and thus it happens that excellent carbons are made in a more or less empirica way. Equally usual is the occasional failure of these empirica methods without assignable cause. Correspondingly common place are the fallacies that do duty for explanatory truths The very word "carbons," as generally employed, is a unfortunate in its way as "tins" for boxes or canister made of tinned iron, and "brasses" for gun-metal bearings. The fact that the discrepancy between the thing and its nam is less glaring than in the instances given makes the term th more dangerous. Commercial carbons certainly do not consis entirely of the element C. True carbon in any of its allotropi modifications is perhaps the most difficult of all substances t obtain perfectly pure, one most cogent reason for this pecu liarity being that solution and volatilisation without chang are in its case well-nigh impossible by any means at presen known. The manufacturer of carbons, cutting his coat accor ing to his cloth, does not attempt the unattainable, but takin approximately pure carbon in a state of fine mechanical sub division, agglomerates it by any suitable carbonaceous materi which, on heating, will decompose with the liberation of approx mately pure carbon to serve as a cement between the particl constituting the bulk of the material. The composition of th resulting moulded carbon depends in the first place on that the commercial variety of carbon selected as the primary ingr dient; secondly, on that of the agglomerating substance chosen thirdly, on the nature of the decomposition which the latte undergoes on heating; and fourthly, on the time and tempera ture of the carbonising process. It is therefore insufficient t regard the quality of the carbons obtained as depending on an physical property; their chemical composition is at leas equally important. To take the simplest example of the nece sity for looking a little deeper than can be done by physica means, it is sufficient to say that few but those who hav actually made the determination have any idea of the quantit of foreign mineral constituents that are left as ash when an ord nary carbon rod is burnt. Where a special need has arisen, suc as that of the makers of aluminium intended to be free from iron, attention has been directed to the one objectionab impurity, but for most purposes no attempt is made to asce tain how much matter other than C exists in carbon rods fo arc lighting or for electrolytic use. Even granting that th amount and nature of the mineral constituents is known, it b no means follows that the balance may be set down as carbon Carbon, prepared by the decomposition of carbonaceous sub stances, retains the elements, notably hydrogen, with which i was associated before carbonisation with great tenacity, and nothing but a complete analysis will give an accurate know ledge of its composition. When this has been done the next

Digitized by Google

step would be to endeavour to distinguish between the various forms of carbon, *e.g.*, graphitic and amorphous, that may coexist in the same rod—a problem of no slight difficulty. With such data as guide, differences in composition of carbons could be recognised as readily as differences in their resistance.

Even when all useful data, chemical and physical, have been obtained, the task remains to correlate these with the properties found most desirable in practice. A method by which to attain this end—quite indefensible scientifically, but promising more tangible results than the strict process of ascertaining the effect of all possible factors alone and together under all conceivable conditions—would be to choose those carbons which have been found of unusual excellence for any given purpose, and to determine every constant at all likely to affect their quality, *e.g,* composition, resistance, specific gravity (apparent and real), hardness and resistance to attrition and oxidation, so that future supplies could be compared with the standard thus created. At present there is an utter vagueness in speaking of the quality of a carbon. Carbons are termed hard and soft, and classed by tentative scratching with a file. There is often confusion between physical hardness and hard-bakedness—if the term may be pardoned—a confusion worse confounded by the partial coincidence of these properties. With a better knowledge of the essential qualities of a good carbon, and the cause of their presence or absence, all looseness of phrase and meaning would tend to disappear. Buyers would be able to say exactly what they wanted, and makers could supply them with a reasonable certainty of satisfying their requirements without undertaking long and costly experiments to decide which grade of carbons would best answer the purpose. The improvement cannot be effected without the expenditure of time, labour, and money; but the interests involved are large enough to make the expenditure ultimately an act of true economy.

ELECTRIC LIGHTING AND TRACTION NOTICES.

The time for giving official notice in the *London Gazette* of Private Bills to be presented to Parliament next Session and of application to the Board of Trade for Provisional Orders expired on Tuesday.

From the following list of notices it will be seen that there are 32 electric lighting notices and 13 traction notices. Compared with the two previous years, the notices are as follows:—

	1891.	1892.	1893.
Lighting	34	20	32
Traction	15	17	13

Of the total of 32 lighting notices 20 are given by local authorities, two by gas companies, and the remainder by electric lighting companies or contractors. Of the 13 traction notices only three are given by local authorities. Most of these propose to use "electricity or other motive power." The Central London Railway does not contemplate any other method of propulsion than electrical, and the Croydon line specifically excepts steam.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, December 1st.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. The following Paper will be read: "The Mechanical Testing of Electro-deposited Films of Metal."

TUESDAY, December 5th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Resumed discussion upon the Papers on:—"Impounding Reservoirs in India, and the Design of Masonry Dams," by Messrs. Clerke, Sadasewjee, Col. Jacob, and Prof. Kreuter. At this meeting the first monthly ballot for Members for the session 1893-94 will be taken.

OLD STUDENTS' ASSOCIATION.

8 p.m. General Meeting to receive Annual Report and Balance-sheet. Address by Mr. Ll. B. Atkinson, "A Trip to Chicago."

WEDNESDAY, December 6th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "An Artist's View of Chicago and the World's Fair," by Frederic Villiers.

THURSDAY, December 7th.

ROYAL SOCIETY.

4 p.m. The following papers are down for reading: (1) "A Dynamical Theory of the Electric and Luminiferous Medium," by J. Larmor, F.R.S. (2) "On Copper Electrolysis in Vacuo," by W. Gannon.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution o[f] Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G. M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; and Joseph Wilson Swan, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied pric[e] 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar o[r] Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

NOW READY.

Volume XXXI. of "THE ELECTRICIAN," price 12/6; post free, 13/6 abroad carriage extra.

Cases for binding Volume XXXI., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

ELECTRIC TRACTION.

Electrical engineers who are looking forward to the development of electric traction are, no doubt, studying the draft regulations which have been submitted for the consideration of the Board of Trade, scrutinising the changes in existing practice which they entail, and the points on which, perhaps, modifications of the regulations may be urged. We do not propose to discuss the regulations at present; they are evidently the outcome of much careful thought, and therefore demand deliberate study. These regulations have not come too soon, for telephonic disturbances have already been experienced, and it is quite possible that some electrolytic damage has been done, though it has not been detected; they have not come too late, for there will be no need to sweep away existing work in the fashion contemplated, and very properly contemplated, by the overhead wire rules.

We did not expect that the Report of the Joint Committee of the Houses of Parliament would suddenly set free a branch of engineering which had been struggling under vexatious

restrictions, nor do we believe that promoters of electric tramlines have been waiting for these regulations before they spread their rails, conduits, and trolley wires over the length and breadth of the land. They are certainly not waiting for some new invention, some ingenious closed conduit, light and inexpensive battery, or novel gearing. They are only waiting until there is some indication of a demand, and a probability that such lines will pay. To import a complete plant for electric traction from some place, say the United States, where electric traction is popular, and to set it at work in some other place, say on the outskirts of Manchester, where there appears to be enough traffic to make it pay, is not to ensure success. The Traction Notices which will be found in another column show that thirteen applications have been made this year for powers to work tramways by electrical or other power. Some of the proposed routes are of considerable interest. The "other power" is not at present a formidable competitor, and we hope that by the equipment and working of some of these new lines the position of electrical power may be strengthened.

The outside car, the hansom, the gondola, the dromedary and the jinrikisca are each a great success, but they do not seem to yield to acclimatisation. No one can tell why the delights of outside cars are confined to Ireland, or why Paris did not appreciate the hansom, and it is almost as difficult to discover why the English public do not demand electric traction. Almost, but not quite so difficult. One reason for their apathy resembles the reason for the deliberate progress of electric lighting in this country. We have good and cheap gas and well-made duplex and other paraffin lamps. Electric light offers a few advantages in coolness and cleanness, but the main question is the price. Similarly, we have excellent roads and street pavement, and the local railway service in the suburbs of our cities is, with the exception of the South London lines, unrivalled. But electric tramways could not greatly relieve the troubles of those who have no choice but to creep up to town on the South-Eastern; for a speed of eight miles an hour, say twice that of a South-Eastern local train, would be considered "furious driving" by the police.

As with electric lighting, electric traction offers certain conveniences, but the main question is the price. It is highly probable that an electric tramway on a fairly large scale could compete with a horse service. No figures about the Leeds Roundhay line nor about the South Staffordshire lines have been published for a long time. The former is unfortunately dependent on holiday traffic rather than on steady daily work, but the latter ought to give some information both as to comparative working cost and as to popularity. We have no doubt that electric tramways will develop, though we believe much more in electric railways. The unanimous evidence of the mayors and other representatives of municipal authorities before the Joint Committee on Electric Powers Protection Clauses showed a strong feeling in favour of cheap traction. A compromise between the slow speed of horse cars and the reckless rush of American street railways would be a service of express cars stopping only at certain points, say three-quarters of a mile apart, running at as nearly a uniform speed between those points as the traffic will permit. A speed would probably be possible such that jumping on or off the car while in motion would be strictly prohibited. Some system of points would be wanted at the turnouts to allow an express car to pass an ordinary car, and these might be worked from either car while in motion, or by the conductor of the ordinary car standing in the turnouts.

It would of course be a great boon if the artisan could live in a neat villa in a smiling suburb, as he does at Pittsburg, and come in by electric tram to his daily work, instead of being housed in overcrowded slums. But as this was not contemplated when the "living wage" was defined, we suppose that the State would be expected to carry him free. It only remains to find the necessary capital to lay down and equip the lines. This difficulty might be solved by the betterment principle being applied to the unhappy inhabitants along the route. They would be annoyed by the clanging of bells, and their children might be run over, but the principle is, we are informed, quite right. Fortunately, however, we have a Board of Trade.

THE CONTINUOUS CURRENT ARC AS A STANDARD LIGHT.*

BY ANDRÉ BLONDEL.

The nature of the continuous current arc has been much discussed, especially of late. The phenomenon which has attracted most attention is the production of the light at the positive crater and the marked fall of potential which occurs at the same time at this surface of passage. The constancy of the intrinsic brilliancy (the light emitted by unit surface) had been announced as very probable by Rosetti, and in a more recent communication Prof. Silvanus Thompson has stated this to be the case on the strength of some unpublished experiments of Captain Abney, and referred it to the boiling point of carbon. Captain Abney used this property to make a standard which he considered suitable for determining the colour of other lights but he did not care to announce it as a standard of light, owing to the variations produced by the flame passing in front of the crater.† Finally, about a year ago, in the course of a discussion at the Institution of Electrical Engineers, Mr. James Swinburne suggested idea, that by placing a screen pierced by a pin-hole in front of the crater it would be possible to construct an absolute standard of light, and Prof. Silvanus Thompson made a few remarks to the same effect. But the authors did not follow up their proposals with experimental proofs, and the echo only reached France when M. Violle‡ undertook a series of experiments on the light of the arc more complete and accurate than those of any of his predecessors, and when I exhibited an apparatus capable of being employed as a secondary standard of light. The experiments of M. Violle were carried out in two different ways, viz., by the fringe spectrophotometer and by photography.§ The learned professor found the brilliancy of the positive carbon to be independent of electric power dissipated (current and voltage). But he did not establish that it was independent of the kind of carbon. To elucidate this point M. Le Chatelier and I carried out some tests on different makes of carbons. As the instrument employed, the pyrophotometer, showed no difference, we thought ourselves justified in concluding, whilst reserving to ourselves the right to make more accurate experiments, that the nature of the carbons had no sensible influence. Later experiments, carried out in the manner described further on, have revealed variations which escaped the pyrophotometer on account of its lack of sensitiveness. These experiments have not, however, modified my conclusions as to the utility and correctness of employing the arc standard as a *secondary* standard for the photometry of arc lamps. I propose in this Paper to detail the reasons which call for the adoption of, or at least for a trial of, this system, and to describe the *modus operandi* and the possible degree of accuracy.

Units and Standards of Light.

It is an error to think, as is sometimes done, that the unit of light can be defined in an absolute manner as a function of the

* Paper read before the International Electrical Congress at Chicago, August, 1893.

† British Association Report, 1882, "On Fixing a Standard of Light," by Captain Abney.

‡ *Comptes Rendus*, January, 1893.

§ The first of these methods only should inspire perfect confidence, since it is only possible to photograph the crater across the arc which rises from it, and this latter, although transparent and hardly luminous, has considerable actinic power, comparable, indeed, to that of the crater itself, and consequently capable of wiping out to a large extent photogenic differences. For my part, even when employing the very short exposures that are necessary, I have never been able to obtain upon photographs the effect of the crater apart from that of the arc.

Digitized by Google

ordinary physical elements, and therefore brought into connection with the C.G.S. system. Light, considered from the photometric, that is to say from the practical measurement point of view, is not a physical but a physiological quantity, and cannot be reduced to the other quantities dealt with by physicists. The unit of light can, therefore, never be defined in any way other than by a concrete standard, and the only measuring instrument used in photometric determinations will always be a normally-constituted human eye.

As a result of the beautiful researches of M. Violle, the International Commission of 1883 adopted as an absolute standard the standard which bears his name, and fulfils all the necessary conditions as to fixity. There is no reason in blaming this standard if the little platinum standards of Siemens, constructed with a view of reproducing it, have not been successes, nor is there any cause to question our choice of an absolute standard. All measurements should be expressed in *bougies décimales*. Each country and laboratory is evidently at liberty to do as it pleases, and employ such and such a lamp as a secondary standard, but on the condition that they transform the figures obtained into *bougies décimales** instead of, as is too often done, taking the secondary standard as a unit.

The Insufficiency of the present Methods and Standards for Arc Light Photometry.

But the Violle standard and the secondary standards at present in use only lend themselves to the measurement of sources of light having about the same tint. As soon as we come to arc lamp photometry we are met by theoretical and practical difficulties. Assuming that one is not stopped by the practical difficulty of equalising two sensations as different as those produced by the two lights on the photometer bar, it is none the less impossible theoretically to estimate in a simple manner the ratio of the candle-powers of two different sources of light. This theoretical impossibility which, *à priori*, renders illusory all the methods at present known, and all that may ultimately be suggested, arises, as is well known, from three main causes, all having a physiological origin.†

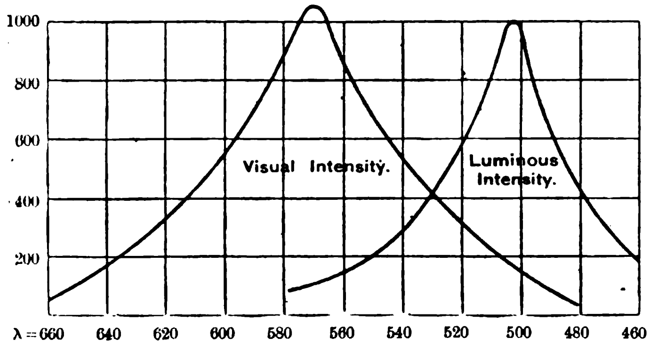

Fig. 1.

(1) A light interests us practically by its luminous and by its visual intensity, that is to say, by the ease with which it allows us to distinguish details. Now, as numerous scientists, and more especially Dr. Charpentier, MM. Macé de Lépinay and Nicati, and Prof. Langley, have shown, these two values do not vary proportionately when we pass from one source of light to another, and the difference is the greater the more refrangible the rays. For instance, Fig. 1 gives the curves showing the distribution according to Charpentier of the luminous and visual intensity in the spectrum.‡ Charpentier holds that vision comprises three distinct processes—the perception of light, the picking out of details, and the perception of the colouration. These results are confirmed, if not numerically, at any rate qualitatively, by Prof. Langley's experiments. A comparison, therefore, of two lights not having the same spectral composition yields different results, according as we measure the luminous or the visual intensity.

(2) The experiments of the investigators whom I have just quoted prove, moreover, that a comparison of two heterochromatic sources of light leads to different results, depending on the dimensions of the surfaces compared. These phenomena are too complex for me to discuss in this Paper.* They were, indeed, partly made known by the famous experiment of Weber.

(3) The intensity of the luminous sensation varies as a function of the absolute luminous intensity, and according to a different law for each colour.† In Fig. 2 I reproduce "sensation" curves for the different colours of the spectrum, based on the experiments of M. Charpentier. It will be observed that the sensations grow less rapidly as the colour becomes more refrangible.‡ This is the well-known phenomenon discovered by Purkinje, and investigated by several experimenters, especially by MM. Macé de Lépinay and Nicati, who have compared the intensity of the Purkinje phenomenon in both visual and luminous perception by successively measuring the amount of light required to produce the same luminous effect, and then the same visual effect as a monochromatic light taken as a standard, the impression produced by it being taken as unity.§ This investigation enabled them to formulate two very important laws:—

(*a*) The ratio of the luminous and visual impressions is independent of the actual intensity in the first half of the spectrum, and only increases slowly with the refrangibility.

(*b*) Beyond the radiation the ratio of the visual and luminous impressions increases very rapidly, and the more rapidly the greater the actual intensity of the source of light.

On account of all these physiological effects it appears without a doubt that the definition of the candle-power of an arc lamp in terms of the candle-power of a yellow or red standard, such as those actually in use is *à priori* impossible‖, and that all methods of heterochromatic photometry are illusory. The result of all of them is merely to shuffle out of the real difficulty by basing the photometric readings on one or two easy determinations with monochromatic light. These determinations once made, they are

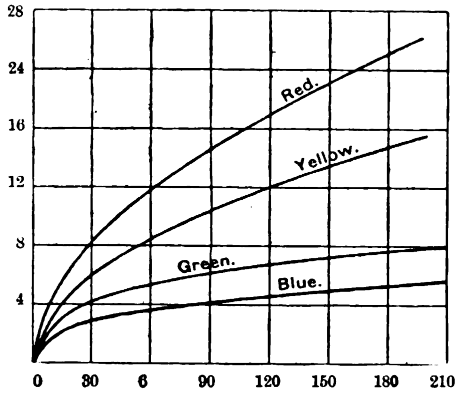

Fig. 2.

multiplied by a suitable coefficient, and a figure representing the so-called candle-power is obtained, and the investigator who wishes for nothing more declares himself satisfied. But the theoretical difficulty is only moved on slightly; it still exists in its entirety in the determination of the reduction coefficient. Moreover, the measurements obtained by several of these methods are rarely concordant.

First of all, if this coefficient has been determined by the method of equal visual impressions (for example, that of M. Crova), it is inapplicable to the comparison of *luminous* intensities. The reverse is the case if the coefficient has been arrived at by the method of equal luminous impressions (for example, that of M. Macé de Lépinay). It is, therefore, always necessary to specify the meaning of this coefficient, unless we make two calculations, one by each method. In the second place, let us see how this calculation has been carried out. In the otherwise ingenious method of M. Crova, the visual intensities of the radiations from the two spectra were set down as a function of one of the radiations, which was taken as unity. That is a very delicate operation, and the figures obtained by different observers do not usually agree well. The curves of visual intensity once obtained it is assumed, according to Roof's law, that the total impression of the spectrum is equal to the sum of the impressions of the radiations; then the two impressions are reduced to the same value by changing

* The use of the carcel is, nevertheless, advantageous in cases where we are dealing with huge candle-powers, such as those of lighthouses. In the case of French lighthouses, in order to avoid unmanageable figures, we express our measurements in carcels of 10 *bougies décimales*. It is under consideration, moreover, to adopt a larger unit of 1,000 *bougies décimales*, and to give it a special name.

† I take no notice of secondary effects, those due, for instance, to the yellow colour of the *forea centralis*, and to the possible "daltonism" of the observer.

‡ *Archives d'Ophtalmologie*, March-April, 1886.

* *Vide* Prof. Charpentier on "Light and Colour."

† This statement is nearly the same as that of Helmholtz.

‡ According to Helmholtz, Macé de Lépinay and Nicati the curves would cut at a certain distance from the origin, which would exaggerate the phenomenon. But Helmholtz's curves are purely hypothetical, and those of MM. Macé de Lépinay and Nicati rest on Fechner's law, which is no longer believed in.

§ The source of comparison was the yellow radiation of the solar spectrum.

‖ Helmholtz has stated ("Physiological Optics," p. 420) that "any comparison of two sources of light of different colour is impossible." Nothing has arisen to invalidate this high opinion since the date of its expression.

Digitized by Google

the scale of the ordinates of one of the curves in order to arrive at the common ordinate. It is this process which is not legitimate, since in virtue of the Purkinje phenomenon the relative impression of each radiation varies with the absolute intensity. In the very seductive method of M. Macé de Lépinay (*Comptes Rendus*, Vol. 97, p. 428), it is first of all assumed in opposition to Kirchoff's theory, which is only applicable in this case to black bodies (*vide* Le Chatelier, Société de Physique, March 4, 1893, p. 134), that "bodies of the same temperature and different emissivities, placed in a dark room, emit light of the same spectral composition," and that consequently it is sufficient to measure two radiations in order to deduce the absolute intensity. But here again, in order to determine the coefficient K, radiations of different tints are compared without taking into account the variation undergone by the ratio by virtue of the Purkinje phenomenon. This coefficient does not, therefore, appear to be determined in a legitimate manner. In the same way it is possible to find the weak point of every so-called heterochromatic method of photometry.

Generally speaking, the expression "an arc lamp of such and such candle-power" has no definite meaning, for it neither indicates how the measurement was made nor to what standard it refers. A first reform would therefore be to demand that all measurements should be made under identical conditions, simply and clearly specified.

(To be continued.)

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.*

BY PROF. GEORGE FORBES.

(Continued from page 100.)

Parallel Working.

Engineers in America have had no experience in actual commercial conditions of parallel working with alternators. This is partly because the machines which have been made in that country do not work so well as some others in parallel. In the case of the transmission from Niagara Falls my opinion is that parallel working will give the best results. If this arrangement were not adopted it is obvious that when the dynamos are loaded up as much as possible they could never be all fully loaded. It is also quite obvious that if our conductors are to be carried through subways the space required becomes quite excessive unless we adopt parallel working. The complete success of parallel working between Tivoli and Rome left no doubt as to the feasibility, besides the desirability, of adopting parallel working. The reduction in frequency which we have made assists very considerably in this result, and it says much for the American manufacturer who has received the contract that, although parallel working with multiphase machines has not been adopted in the past, he is ready to guarantee the performance in this respect of the machines which are to be built for us.

The rules which govern the construction of machines which shall work well in parallel are not very clearly understood. The only fact which has been perfectly established in practice is that the lower the frequency, the more efficient and sure is the parallel working. It certainly depends to some extent upon the amount of self-induction and the amount of mechanical momentum in the machines. It is also certain that if the self-induction of the machines is too high they will not work well in parallel. Of all machines which have been constructed, those which work the best in parallel appear to be those of Ganz and Co., Mordey, and Elwell-Parker, but there are many others which do extremely well. It is, at present, not possible to state exactly the conditions which are necessary, but I may say that, generally, a machine with a stiff magnetic field works better than one where the iron is far below magnetic saturation. In judging whether a machine of a particular type will or will not work in parallel, I think one must be generally guided largely by one's own personal experience in the matter, combined with a knowledge of the effects of self-induction, mechanical momentum, and magnetic saturation as deduced from theoretical considerations. I do not think that anyone who knows anything of the working of the Tivoli-Rome plant would for a moment hesitate in saying that on a large and important station like that at Niagara Falls parallel working is essential; and this is the opinion of Prof. Mengarini, who has so ably directed the works at Rome.

Motors.

Under this section it may be as well to discuss some of the different purposes for which the electric current will be required. With regard to arc and incandescent lighting, if the frequency be high enough, the current can be used directly for this purpose; although most people would prefer that, in the case of arc lighting, the current should be commutated or converted in some manner, so as to give a continuous current. That this is unnecessary, however, is amply proved by the perfect success of the arc lighting by alternating currents in Rome and many other large cities, especially those which have been established by Messrs. Ganz and Co. At the present time, one of the largest applications of electricity in the United States is for street railways, which require a continuous current. Another similar purpose which we shall have to consider is the application to canal boats, since it is intended to work the Erie Canal by electricity. This canal starts from the Niagara River, and reaches the Hudson River at Albany, 350 miles distant. For these purposes some sort of commutator or motor transformer will be desirable. Some of the first work which will be done is the supply of much direct current at 150 volts for the production of aluminium. This also requires the continuous current, and similar means must be used for obtaining it. Among the large class of mills which will be established at Niagara Falls, one of the most important kind is wood-pulp mills, one of which is already working on our land, and will be the first to receive water-power from our canal. This type of mill uses many thousands of horse-power, and is worked continuously day and night. In this feature it resembles, probably, a large number of the mills which will take advantage of the cheap power at Niagara Falls. Such mills are working continuously day and night, and do not require to be ever stopped or reversed. This is an important class of work in our case, because current can be supplied to such mills by means of synchronising alternators whose efficiency is extremely high, and this may, perhaps, be done in some cases without transformers. We require also to consider the case of small motors for use in shops, and for elevators, cranes, and a large number of other purposes. In this type of motor frequent stoppings and reversals are necessary. Hitherto direct-current motors have generally been employed for this latter purpose, but the rotating-phase induction motors are distinctly suitable, and when these have been fully developed they will probably be largely used for this purpose. The commutated current is a thing which is sure to be in common use before long, and although our arrangements at Niagara Falls are perfectly complete without a machine for this purpose, still its employment has been considered by us, and the probability of its future use has influenced our judgment in some points. There are so many purposes for which the direct current is most convenient, that people would generally accept it for transmission if it were capable of being economically transformed up and down to different pressures. The direct-current dynamo is really an alternating dynamo with a commutator placed upon it. If the commutator, instead of being placed there, be placed in the neighbourhood of the motor, we obtain most of the advantages both of the continuous and of the alternating current. This is one of the advantages of having two phases generated by the dynamo, because it is much easier to rectify a two-phase current than a single-phase current. In addition to the motors above specified, there are a large number of single-phase motors which start with a powerful torque which have been invented by different electricians, but which are not yet put upon the market. There are also machines with commutators like a direct-current dynamo with laminated field. These all become very efficient and useful when the frequency of alternations is sufficiently diminished.

Line Construction.

A great deal of attention has been given to the different methods by which current can be conveyed to the points of consumption, whether on our own property or at Buffalo, or even further. Naturally the pole line was first dealt with, in which the poles might be constructed of either wood or iron. This is the cheapest type of construction, and has some advantages, but we must consider the climatic conditions in the neighbourhood of Niagara Falls. We are subject there to severe thunderstorms, and troubles from lightning have already been serious in several parts of the United States in connection with electrical machinery. Snow and frost are very severe, and sleet forming upon the wires and insulators may cause a great amount of trouble. There are also at times very violent gales sweeping from over Lake Erie. All these difficulties can be counteracted to some extent, but it is nearly certain that with overhead construction occasions would arise when the continuity of operations would be interrupted, and this would be a very serious matter. The next system to be considered in order of cost would be underground cables, but I am strongly opposed to the adoption of these for any considerable length. It is true we are able to deal with their capacity so as to reduce its injurious effects, but surely the best plan of all is to abolish the capacity itself as far as possible. The most satisfactory method of proceeding is to build a subway of sufficient size to enable a person to walk along it and to carry bare copper conductors in it, but this a matter of considerable expense. I am glad, however, to be able to inform you that the officers of the Company resolved last summer that a subway such as I have

* Paper read before the Institution of Electrical Engineers November 9th.

Digitized by Google

described should be constructed from the power-house up to the Pittsburg Reduction Company's works, where aluminium is to be produced, a distance of 2,500ft. In accordance with their instructions I prepared plans, which are now exhibited, and which give space enough to carry the conductors at 20,000 volts for all the power that will be developed by the present tunnel, parallel working being adopted. The subway is built of concrete having a minimum thickness of 10in. The height inside is 5ft 6in. Wooden beams are embedded in the concrete on both sides every 30ft. When the concrete is set these beams are removed, and iron castings for supporting the brackets that hold the insulators are put in their place, and these are then grouted in. Iron brackets, as shown in the drawings, are bolted to these castings, and the oil insulators placed upon them. Copper wires are shown as being supported on these insulators, but we shall probably adopt copper strip. The bottom of the subway is always on an incline, and is of curved shape to drain off any water of condensation, but it is also proposed to force air through the subway so as to keep it dry. The 2,500ft. now being completed is all drained at the power-house end by a boring into a water-bearing stratum. At the bottom of the subway the concrete is formed in two steps, the lower one of which supports sleepers for a very light tramway upon which a truck can run to carry supplies, and also to carry the inspector. At first this can be moved by a hand lever, but arrangements are made for eventually driving it by electricity, the conductor being carried on the floor, between the stringers (placed on the ties or sleepers), which form a platform running along the length of the subway. On the stringers outside the rails is placed a screen separating, mechanically and electrically, the part of the subway where the conductors are from the part where the inspectors walk. This screen is formed in 10ft. lengths of wood supporting expanded metal, covered over with plaster up to a height of within one foot of the top, the upper part being left open in the form of a network, through which the inspector can look at the conductors and their supports. These screens are held by iron supports fixed by expanding bolts into the concrete, and can easily be removed. The top of the arch is 3ft. below the surface of the ground, so that it will not be affected by frost. According to the last report, it appears that on October 21st 1,590ft. of this subway had been completed; the total length being put down at present is 2,500ft. Each of the iron castings has a wire attached to it which passes through the concrete, and is soldered to a copper wire running outside the subway along its whole length, and connected to a plate sunk in the water at any suitable points. At every 400ft. cross streets will be made, and at these points there is a manhole. Also at these points, on each side of the subway, four drain pipes, 3in. in diameter, are let in, closed at their outer ends. When the subway is to be tapped for use on the side streets, or for intermediate points, wires can be laid through these pipes. Between Niagara Falls and Buffalo there is very little rock, but the part where the subway has now passed through has been chiefly in rock. This involved blasting out a channel larger than was required. In this case the part of the trench outside of the subway has been built up of stone. In the construction of this subway American Portland cement has been used, and a very suitable sand from the neighbourhood, which contains its own gravel. The whole of this work has been done by Mr. Humbert, and up to the date of my last inspection every part was thoroughly and satisfactorily done. This work is of great importance as conveying to the minds of those who intend to use our power some idea of the desire to ensure continuous working.

With regard to the electric pressure that is to be used for distant transmission, this will undoubtedly advance with experience. Some manufacturers in Europe who tendered for the work proposed to adopt 25,000 volts; but we have considered that at present 20,000 volts is not likely to be exceeded by us, and we may work at a lower pressure at the commencement. When it is remembered that the Deptford machines have one terminal connected with the earth, and are working satisfactorily at 10,000 volts, and when it is noticed that, in consequence, our work would be under exactly the same conditions as regards insulation when working at 20,000 volts, it is easy to see that we are not risking anything experimental in our first work.

With regard to the size of conductors, I worked out the economical size at different current densities for the whole distance. In doing this I took the following data:—I took the cost of copper at 12½ cents per lb., and the annual charge on this cost at 5 per cent. I then computed the power loss in the line, and the amount of power which was left available for delivery. I took the value of this power at the distant end of the line as being $15 per horse-power. This is something more than what it costs us to produce it, but when the power available from our tunnel is nearly all consumed this quantity will have to be increased. It must also be remembered that I have not allowed for the increased size of the conductors required by the retardation of phase, which is an unknown quantity. Still, it will be seen that from these considerations we may be able to work economically at a slightly higher current density than is obtained from this investigation. From this work it appears that the most economical density to work at is 350 amperes per square inch. If this density is used, the fall in volts between Niagara Falls and the northern boundary of Buffalo is only 3½ per cent.—a matter which makes regulation extremely easy.

With regard to the efficiency of the system, it is remarkable how high the efficiency of the dynamos comes out when we are dealing with the large units of 5,000 H.P. There can be little doubt that the efficiency, electrical and mechanical, of our dynamos may reach at least 98 per cent. Taking off 3½ per cent. for losses on the line, we would have 94½ per cent. delivered electrically at Buffalo if no transformers were required to raise the electric pressure to the full 20,000 volts. In cases at Buffalo, where the power consumed is very large, the motor can be constructed on the same principles as the dynamo; and if in this case it be ever possible to work at the full pressure without a transformer, it is obvious that the total efficiency of the system—that is, the power delivered by the motor to the shaft of the machinery, divided by the power delivered by the shaft of the turbines to the dynamo—will be certainly over 90 per cent. As a matter of fact, if we were to use a higher density of current, and were to use step-up transformers at Niagara Falls and step-down transformers at the northern boundary of Buffalo, and other step-down transformers in the town of Buffalo itself, and were to use motors of small power, and consequently less efficiency, in this case the total efficiency of the plant might be reduced to 80 per cent., or even lower.

I have given these figures, not as indicating precisely the lines on which we have determined to work at Buffalo, but because the present Paper is intended to embrace the subject of the general distribution of power, and I thought it desirable to lay before you certain facts in this connection in a definite form.

Description of Machinery to be used.

Under this heading I shall deal chiefly with the type of dynamo which has been finally decided upon. It will suffice to say of the turbines that they are each of 5,000 H.P., that they revolve at 250 revolutions per minute, and were designed by Messrs. Faesch and Piccard, of Geneva. All the principal parts of this machinery were constructed by the I. P. Morris Company, of Philadelphia, but the governors of the turbines are of Swiss manufacture, and part of the steel fittings were constructed in France.

With regard to the dynamo, the Cataract Construction Company at first invited many different manufacturers in Europe and America to submit plans. The number of these that were submitted altogether amounts to 24, some of the manufacturers having taken a great deal of trouble to submit a series of designs, in order to be able to meet different requirements. Many of these designs were extremely good; but it was determined, after estimating the increased cost of using the European designs, owing to the high tariff in America, and owing to transport, to have the machines manufactured in America. Among the designs from American manufacturers there were none which fulfilled all the requirements of the case, and eventually the Cataract Construction Company decided to get out their own designs, and to submit them to the American manufacturers for tender. I had been for some time previously engaged in working out a design which I am confident none of the manufacturers who had sent in designs could say was in any way borrowed from their ideas. We had received suggestions of an external armature with internal revolving fields, and also of external fixed fields and internal revolving armature. We naturally had a preference for a dynamo with a fixed armature, because the coils can be more securely wound, and are not subjected to the mechanical stresses induced by centrifugal force. But all the designs with revolving fields which had been submitted to us contained a weak feature: the field coils were held in by pole faces secured by bolts or keys to the poles, and this seemed an element of weakness when we considered the enormous centrifugal forces to which the machinery would be subjected. At the same time the turbine makers had insisted upon having a certain momentum, or fly-wheel effect, which was not given by the revolving parts of any of the dynamos submitted to us, and it was found that if anyone of these had been accepted it would have been necessary to add to the design a fly-wheel of large dimensions. Centrifugal force was one of the most important matters to be considered, because at 250 revolutions per minute this force assumes considerable magnitude in the large masses with which we had to deal. Moreover, in all the designs which had been submitted, the magnetic pull between the poles and the iron of the armature assisted the centrifugal force. The principal feature of the design upon which I was working, consisted in having the armature fixed, and inside the machines, with the fields revolving outside; the fields being formed of a ring of iron with the poles projecting radially inwards. One advantage is that we are able to get the full fly-wheel effect that was required by the turbine makers. This requirement was that in the revolving part the sum of the weight

Digitized by Google

in pounds of each part, multiplied by the square of its velocity in feet per second, should equal 1,100,000,000. The design also gives an extremely good mechanical construction for the revolving parts. The iron ring which forms the yoke of the fields serves as a support to hold in the pole-pieces and the exciting coils, and no part is held in against centrifugal force by bolts or keys. Moreover, the magnetic pull between the fields and the armature acts in opposition to, and does not assist, the centrifugal force. The armature is fixed, and a large space is available inside it for the workmen to attend to the bearings, and to reach any part of the armature. It is obviously possible to insulate the armature coils for any electric pressure. With a large machine of this kind, the space occupied by insulation has not the same importance in reducing the output of the machine as is the case with machines constructed in the past. In fact, the armature coils can be wound with the same insulating properties as a transformer, and hence the necessity for using a step-up transformer can be avoided.

Starting with this general principle, I first got out designs of a machine at 33 periods per second, in order that I might compare the general appearance of such a machine with those of other types. The next point was to design a machine of as low a frequency as was possible under the limiting conditions as to weight. The revolving parts of the turbine and dynamo, and the shaft connecting them, are supported by a hydraulic piston, and it was the desire of the Cataract Construction Company not to use a thrust bearing of any kind to support the weight, although there is a thrust bearing at the top of the shaft, which simply acts to retain the apparatus in a fixed position in a vertical direction. Owing to this decision, it was necessary to limit the weight of the revolving parts of the dynamo to 80,000 lbs. In getting out the design for this machine it was desirable to select such a form of winding as past experience led one to believe would be most efficient for parallel working, and I judge from past experience that this is best attained by having the number of coils per pole very small. The 33-period machine which is shown in the drawings has only been sketched out with a view of getting at the general dimensions of the machine. It is not suitable for our special purpose, because it is essential that, without taking the dynamo altogether to pieces, we should be able to lift up through the centre of the dynamo any parts of the turbine shaft which may require repair.

It will be seen that from the necessities of the case at Niagara Falls, the dynamo which was required differed in some respects from what would be necessary in many other cases, but it is equally obvious that in any case of so large a transmission of power the conditions must be thoroughly considered beforehand, and the dynamo specially designed for the purpose. At the meeting of the Board of Directors of the Company, in May, 1893, I was instructed, with Dr. Sellers, to get out plans for an alternator of the type which I have described.

I am not able to lay before you now plans of the machine as it has been finally adjusted by conference between ourselves and the manufacturers. In the plan which we prepared, the frequency was 16⅔ periods per second, there being eight poles. The armature coils were so wound that they might be connected to give either 2,500, 5,000, 10,000, or 20,000 volts, and the coils were limited in number so as to give the best assurance of good parallel working. For various reasons we decided eventually to raise the frequency to 25, and to lower the volts to 2,000, without the means of connecting the coils to give a higher pressure; and instead of winding the armature on the conductors in a limited number of coils, to adopt the methods more commonly used in some of the large types of generators. But since in any future work which is done, the dynamo will be required to be modified for the special purpose, a description of the machine—of which I am able to show you the drawings†—is sufficiently representative of the type of machine for our purpose.

General Description of a 5,000-H.P. Alternator.

On the bed-plate a vertical cylinder is bolted, with projections to support the fixed armature and the bearings of the revolving part. The armature coils are wound independently and can be removed and changed. They are fixed in slots in the fixed armature. They are encased in an oil-tight casing through which oil can be circulated. The field magnet is external to the armature, and has the poles pointing radially inwards. It consists preferably of forged steel supported by a spider with eight arms, which may be of steel with a covering of thin sheet metal, on which cups are provided for forcing air into the interior of the machine. The pole-pieces are bolted on to the steel rim. The field coils are of copper strip, two coils being wound upon each pole, with a space between them for air circulation. The exciting current is applied by rings of tempered copper on the spider, having fixed brushes rubbing on them. The hub of the spider is firmly fixed to the upper end of the shaft. The spider supports the heavy rim by 16 studs and nuts. The shaft is supported by two bearings, each of which has four radial arms, which are bolted to four corresponding projections on the cast-iron cylinder. This cast-iron cylinder is bolted to the bed-plate, and adjusted thereon by wedges. Besides having on it the projections for carrying the bearings on its inner side, it has on its outer periphery a series of vertical ribs against which the stampings, or sheets of iron forming the armature, rest. It also supports the lower end plate on which the armature is built up, and the armature is keyed to it by a single key. The armature is wound drum fashion—that is, all on the outside. This enables the coils to be wound independently and laid in their place, and also to be easily replaced in case of accident. In order to do this satisfactorily, the slots for each coil in the iron are cut, not radially, but parallel to each other. Each coil is encased in insulating material, which forms a tube through which oil may flow as in a transformer, but may be forced, in which case its circulation is maintained by a pump. Round the base of the machine there are two oil pipes, one being the inlet, the other the outlet. The inlet pipe is connected with a reservoir of oil in the power-house. The outlet pipe leads by another pipe to cooling arrangements in running water, from which the oil is pumped to the reservoir. From the inlet pipe 16 brass tubes are led to the junction boxes at the bottom of the 16 coils; the 16 other brass tubes are led from the junction boxes at the top of the coils through the interior of the fixed armature and bent over the foundation plate, and so connected to the outlet pipe which surrounds the bed-plate. The bed-plate is a single iron casting, and in order to enable it to be transported over the railways it was necessary to limit its diameter, as shown in a supplementary drawing, which shows the improved oiling arrangements, which were worked out by my chief draughtsman at Niagara Falls, Mr. Baumann. The armature is built up of thin sheet iron, with ventilating spaces, as shown on the drawing. The bolts which hold the armature together are eight in number, to be made of nickel steel, a metal which has the great advantage of being non-magnetic, and of very high electrical resistance and great mechanical strength. The amount of nickel is 25 per cent.

There are 16 armature coils, eight being of one kind, called "short" coils, and eight of another kind, called "long" coils, the length of wire on each coil being the same. The short coils are bent over at the end plate, and the long coils are wound in one plane, and enclose the short coils. I find that if we are to have a very stiff field, with first-class quality of iron in the fields, each coil would consist of 72 turns of pure copper wire, No. 0 of the Brown and Sharpe gauge, which gives a very low density of current, and reduces the heating. In fact, it has been my view that in designing the machines for so great and permanent a work every effort should be made to reduce the rise in temperature, even to far below what has ever been done in the past. The unequal expansions and contractions of materials in a machine of this kind are very injurious to its permanence, and affect the insulating material seriously. The layers of wire in the coils are separated by mica. Each coil when wound has strips of insulating material laid spirally round it, so that oil may circulate freely in the intervals, and the whole is encased in a casing of strong insulating material. The material which I prefer for this purpose is certainly woodite, an eighth of an inch of which will not break down with 30,000 volts, and which is not acted upon by oil even at high temperatures. I have a record of tests with oil which are conclusive on this point. It is quite the best material I have seen for the purpose, though costly, and, being a secret process, it may be difficult to ensure uniformity.

The frames of the bearings are of cast iron, with four radial arms, which rest upon four projections cast on the vertical cylinder, and are bolted to them. By this means, when the field magnet with the shaft have been lifted out of place, the bearings can be twisted through an angle of 45 degrees in a horizontal plane and then raised out of place, leaving a space of five feet in diameter through which portions of the turbine shaft can be raised for repair. The bearings are oiled at the centre by oil forced under pressure through a pipe. The oil is then distributed over the bearings by spiral grooves. A spiral groove is also cut in the hub of the frame, with a pipe at each end to admit of water circulation to cool the bushing. At two opposite sides of each bearing the bushing is made thin, and a rod of bismuth is soldered thereto; so that if the bushing is heated a thermo-electric current shall be created which, by means of a relay, can ring a bell in the power house. When this occurs, water can be immediately admitted to cool the bearings, and the attention of the workmen is drawn to the necessity of an examination.

One of the parts which required most consideration was the material of which the spider supporting the field magnets should be constructed. The best plan is to make it of steel, for the sake of lightness, and to cover it with a copper covering, which might, I think, be spun; or, perhaps better, electro-deposited nickel might be used.

† [Diagrams were shown at the meeting, but none of them have been received by us for publication.—Ed. *E.*]

Between the pole-pieces the space is filled up with a screen or plate of metal so as to direct the air ventilation only upon the parts which most require cooling.

The methods finally selected for oil circulation are shown in a separate drawing.

It will be obvious from this design, considering that the speed of revolution is 250 per minute, that great care has to be devoted to the balancing of the revolving parts ; everything has to be calculated not only for a speed of 250 revolutions, but for double that amount, which is the maximum speed at which the turbines could possibly run—at which speed they might run through a breakdown of the governor, although this is an accident almost impossible to occur. Each of the revolving parts will of course be balanced individually, and I have suggested a plan for the final balancing which seems likely to be effective. A temporary bushing would be put in the bearings, of india-rubber lined by a thin metal tube. The dynamo would then be rotated slowly and the balance adjusted in the usual way. The speed of revolution would be gradually increased—a new adjustment being made at each speed—until a speed of 500 revolutions a minute is attained, and when an adjustment has been made at this speed it is pretty sure that the balance at 250 revolutions per minute will be very perfect, and the mechanical friction reduced to a minimum.

As stated before, the oiling arrangements have been introduced not only to ensure higher insulation and to preserve the insulating material, but also to lower the temperature as much as is possible, because every step we take in the reduction of temperature is an advance. These oiling arrangements may perhaps be adopted in the future, but at present we are not making use of them in the machines which are in process of construction. When we have had experience with these we may in future adopt the oiling arrangements ; and as there is likely to be a great development in the direction of electric transmission of power in connection with the utilisation of water power in many parts of the world, it has seemed well to me to put before you these details, so that they may be considered in other cases that may arise.

At a meeting of the Board of Directors in New York lately it was resolved, on the recommendation of the consulting engineers of the Company, that the contract for two or three alternators, each of 5,000 H.P., should be assigned to the Westinghouse Electric and Manufacturing Company, of Pittsburgh. I would wish to state how much we owe to Mr. Westinghouse, and to his chief engineer, Mr. Schmid, for the zeal with which they have taken this matter up, and their desire to meet our views and to secure for us machines of which they felt they could guarantee the satisfactory performance.

Before leaving the subject of the dynamo, I would wish to point out that it has been designed for special circumstances in connection with the Cataract Construction Company's work. If a dynamo of the same type were being constructed for another place, it is certain that modifications would have to be introduced. I particularly draw attention to the fact that some trouble in getting out a good mechanical design arose from the necessity which existed of being able to provide a clear space of about 5ft. diameter in the middle of the machine without taking the whole machine to pieces, the object of this being to enable us to lift up portions of the turbine shaft which it might be required to put into repair. In any case, where the long shaft existing in our case is not required, the design of the dynamo is much simplified, and would more nearly approximate to the first design of which a drawing is shown, but arranged for 33 periods a second.

If the present Paper were intended to relate solely to the subject of the utilisation of power at Niagara Falls I would be content with describing what has actually been done; but I foresee that there is going to be a great development in utilisation of water-power and its electrical transmission. I am, therefore, inclined to say a few words on some other details which we have been carefully considering, but about which no definite decision has been arrived at.

Before doing this I would direct your attention to the drawing representing a plan of our power-house, in which you will perceive the inlet passages, A, from the great canal, B, which draws its supply of water from the upper river. From these inlet passages the iron pipes, or flumes, C, pass vertically downwards to the bottom of the great wheel-pit, which is a slot cut in the ground to a depth of nearly 200ft., at present large enough to contain four turbines in line, but which can be extended to a much greater length, the whole capacity of our tunnel being 100,000 H.P. The drawing shows circles, D, in the plan, which indicate the position of the turbine and dynamo above it, and the position of a hatchway, F, by which material can be raised or lowered. It will be noticed that between the inlet channels and the wheel-pit the flumes are bent downwards, and thus leave a V-shaped space, G, which I have appropriated to make a subway, running along the whole length of the power-house, to carry the high-pressure conductors. It will, of course, be understood that the slot forming the wheel-pit is arched over at the top to form the floor of the power-house, upon which the dynamos rest. It will be noticed that at the north end of the power-house there is a large square chamber, H, in which I propose that all the measuring instruments and other apparatus under the control of the chief electrician shall be assembled. Underneath this chamber there is a cellar in direct communication, first, with the subway which I have described as existing in the power-house ; and, second, with the subway which leads outwards from the power-house at present as far as the Pittsburgh Reduction Company's works, and may possibly eventually lead to Buffalo. In this cellar all the high-pressure wires, the transformers, the artificial load, and other high-pressure machinery will be placed. It will be noticed that other spaces are left in the floor forming trenches along which the conductors can be carried. With these arrangements there can be no possibility of danger to any person in the power-house ; and if any wires are to be found laid along the walls of the power-house or elsewhere, I wish it to be a maxim that we shall be able to place upon these wires a card marked "No Danger," so that there will be no possibility of danger from any person touching anything in the power-house.

With regard to the exciting current, the best plan available at this moment is to use one of the machines which are generally known as the Schuckert machines, for converting the alternating into a continuous current, transformers being inserted in order to lower the pressure. In order that the exciting current may increase with the load, it would be well to make these transformers of special construction, each having two primaries and one secondary. One of the primary coils would be in series with the main circuit, and the other in shunt. I would furthermore make these transformers sufficiently large to deal with all the dynamos which are in the central station, and I would subdivide the secondary coil into sections, to enable us to cut out a section of the transformer when we cut out one of the dynamos. When we wish to cut out a dynamo, a switch would be worked which would at the same time short-circuit the field coils of that dynamo and also cut out one section of the secondary of the transformer which is supplying the exciting current to all the dynamos. This plan allows the fields of all the alternators to be put in series—a desirable arrangement for parallel working. A resistance may, of course, be put in circuit with the fields of the alternators for regulation.

I presume it will be taken for granted that in any large work of this sort the primary circuit should never be broken when in action. For my part, I hold that this should be the case even in smaller stations.

An important feature for putting the dynamos in parallel, and for removing a dynamo, is an artificial load. It is desirable that this artificial load should consist partly of a resistance and partly of self-induction. It is only by this means that the dynamo which is going to be put in circuit can be brought to exactly the same condition as those which are working, both as regards volts and amperes. It may be well to describe the operations which take place when a dynamo is switched in parallel with the others. First, connection is made between the armature and the artificial load ; then the exciting switch is turned so that an extra section of the transformer is put into play, and the short-circuit on the field coils of the dynamo is broken. The dynamo being excited, the turbine is then started, or this may be done at first. The artificial load is then adjusted until the dynamo is giving the same volts and amperes as the others. A synchroniser is then placed between the artificial load and the external circuit, and so soon as synchronism is attained a switch is closed which connects the artificial load with the external circuit. Resistance is then put into the artificial load until there is very little current going through it, when it is switched out, and the dynamos are all working in parallel. To cut out a dynamo from the circuit the operations are performed in the opposite order. The artificial load with high resistance is put in connection with the external circuit ; this resistance is gradually diminished until it indicates the amount of work that is being performed by one dynamo ; the connection between the artificial load and the main circuit is then broken, leaving the dynamo (which is being switched out) feeding the artificial load. The resistance of the latter may then be increased, and the exciting switch actuated so as to short-circuit the fields of the dynamo, and to remove one section from the secondary of the exciting transformer. The supply of water to the turbine may then be shut off.

If machinery is worked, even at 20,000 volts, in the manner I have described, there is no possibility of injury from any great rise of electrical pressure, unless the external circuit be by any means accidentally broken. To provide against this sort of trouble I would have wires coming from the external circuit where it enters the power-house, connected through a large resistance, or through the primary of a transformer the secondary of which contains a resistance. In circuit with it I would have a break consisting of two carbon points at a distance of about half an inch apart if we were dealing with 20,000 volts, so that an arc could not be formed unless the pressure rose above the normal value. Under these circumstances, so soon as any resonant effect due to the

Digitized by Google

breaking of the circuit or due to any other cause raises the electric pressure above the normal, an arc is established across the carbon points, and so a load is put on which removes the cause of the extra high pressure. This is the only automatic means which I have been hitherto able to think of which is sufficiently rapid in its action to overcome any possibility of injury to the dynamo or transformers.

I have attempted in the course of this Paper to give you some idea of the work which has been actually done or decided upon at Niagara Falls, and also to show you the views to which I have been led by any special experiences which I may have had as to the general ideas which ought to guide us in the construction of plant in the future for transmitting power to a distance electrically.

In describing the different plans which are available I have avoided mentioning the names of those numerous electrical engineers and manufacturers who, by their inventions, researches, or applications have advanced the art; or discussing their claims to priority; but I cannot conclude this Paper without mentioning the names of some of those who, in one way or another, have made great steps in the applications of alternating currents to power purposes. I would particularly mention the names of Messrs. Ganz and Co., Mr. Schuckert, the Allgemeine Electricitäts Gesellschaft (of Berlin), the Oerlikon Fabrik, and Messrs. Brown, Boveri and Co.; also Mr. Eickemeyer, Mr. Ferranti, Prof. Ferraris, Prof. Fleming, Dr. J. Hopkinson, Messrs. Hutin and Leblanc, Mr. Rankin Kennedy, Prof. Mengarini, Mr. Mordey, Mr. Tesla, Prof. Elihu Thomson, and Mr. Henry Wilde. I feel that all of us owe a great deal to their work.

In conclusion, I wish to draw attention to the figures which show the relative merits of high and low frequency with polyphase motors.

Everything is identical in the two figures, except that, the frequency of one (*a*) being double of the other (*b*), *a* has 16 poles, *b* has 8. The armature is identical in both, and revolves at the same speed and does the same work; and the field revolves at the same rate in both, and the induction and current-density are the same. The differences are that *a* has more copper and less iron than *b*. The comparison of efficiency depends on the depth of both. As an example, assume that *a* has 50 per cent. more copper in the fields than *b*, the ampere-turns per pole being necessarily the same in both, and that *b* has 50 per cent. more iron than *a*, and that the hysteresis loss in *b* ($=H_b$) is equal to the resistance loss in its copper coils ($=C_b$). The values for *a* are—

$$H_a = 2 \times \frac{2}{3} \times H_b;$$

$$C_a = \frac{3}{2} C_b;$$

$$H_a + C_a = \left(\frac{4}{3} + \frac{3}{2}\right) \frac{H_b + C_b}{2} = 1{\cdot}42 \times (H_b + C_b).$$

Thus the total losses in the field of higher frequency (neglecting eddy-currents) are 42 per cent. more than in the field of lower frequency.

PHYSICAL SOCIETY.

At a meeting of this Society, on November 24th, Prof. S. P. Thompson occupied the chair, whilst the President read a Paper

"On the Magnetic Shielding of Concentric Spherical Shells."

In this mathematical investigation the author considers cases in which the equipotential surfaces are surfaces of revolution about a line through the centre of the shells, and the permeability (μ) of each shell is constant. Taking the common centre as origin, the potential within any shell is expanded in terms of zonal spherical harmonics, and the ratio of the shielded to the unshielded field determined. The following important result is arrived at, viz., if the permeabilities of the enclosed and external space be the same, then the ratios of the shielded to the unshielded fields are the same *for each harmonic term*, whether the part shielded be external or internal. It is also shown that the shielding effect on external space when a small magnet is placed at the centre of the shell is the same as the shielding effect on the enclosed space when the shells are placed in an uniform magnetic field. If the inner and outer diameters are given, then, when the difference in these diameters is small, one continuous shell gives the best result. For a larger difference two shells separated by an air-gap are much more efficient than a single one, and filling up the air-gap would appreciably diminish the screening effect. When the permeability of the substance is high the best shielding is obtained when the radii of the bounding surfaces of the shells are in geometrical progression. The main results of the investigation are that with thin shells lamination is useless, whilst with thick shells it is essential, if the best effect is desired. Experiments made on actual shells had fully confirmed the theoretical conclusions.

DISCUSSION.

Prof. MINCHIN said: Although the work was apparently restricted to zonal spherical harmonics, some of the important formulæ apply equally to general spherical harmonics. He thought that the Paper was very clear.

Mr. EVERSHED said he had been engaged for the last two years on the subject of magnetic shielding, with a view to screening measuring instruments from external fields. In such cases it was not possible to use closed shells, and this introduced trouble. The best result he had yet obtained was to reduce the disturbance to about one-fifth. Another difficulty was introduced by the fact of the shield being magnetised by the current passing through the coil, and, owing to hysteresis, the permeability was different according as the magnetisation increased or decreased. By using an outer iron shell a great improvement had been effected. To obtain the best results it was important to have no joints in the shields. A coil frame with two shields of bent iron was exhibited.

Mr. J. SWINBURNE remarked that the subject divided itself into two—shielding of instruments and shielding sources. If a dynamo itself be shielded this did not prevent the currents in the leads producing magnetic disturbances. This was very important in ships. By using an alternator with revolving fields all disturbances could be avoided.

Dr. C. V. BURTON inquired whether, by considering the hydrodynamical analogue of a porous material, the case of perforated shells could be elucidated.

Mr. A. P. TROTTER asked whether Prof. Rücker's investigation could be applied to the homogeneity of the shield. Small scrap iron had been used at Oxford as a magnetic screen in preference to boiler plate.

Mr. BLAKESLEY asked if the effect of moving a magnet sideways in a sphere had been observed.

Prof. S. P. THOMPSON thought that taking the permeability as constant would not be quite correct, for μ was a function of the magnetisation. Hence, in the cases considered, the outer shell would be the more permeable.

In his reply the PRESIDENT said scrap iron in contact was not like clear space, for there were comparatively free paths for the induction at the points of contact. As regards the shielding of the dynamo at Greenwich, Mr. Christie had written to say that the credit was due to the makers of the machine and shields, Messrs. Johnson and Phillips.

Prof. G. M. MINCHIN, M.A., then read a Paper on

"The Action of Electromagnetic Radiation on Films containing Metallic Powders."

After noticing the resemblance of the phenomena exhibited by tubes containing metallic filings shown by Mr. Croft on October 27th, to those of photoelectric impulsion cells, he described films of gelatine and collodion containing metallic powders. Directions for preparing the films are given in the paper. On inserting such a film in circuit with a battery, key, and galvanometer it acts as an insulator. To render a small portion conducting, the electrodes on the surface of the film are brought very close together, and one of the wires touched with an electrified body. (An electric gas-lighter was often used.) This caused a current to pass. The electrodes may then be separated a little further and the process repeated until any desired portion is rendered conducting. The peculiarity of such a film is that, if the circuit be broken at the film, the film becomes an insulator, whereas breaking the circuit at any other point leaves the film conducting.

A short discussion followed, and Prof. MINCHIN, in his reply, maintained that the phenomena were due to electric impulses.

LEGAL INTELLIGENCE.

Electric and General Contract Corporation v. Thomson-Houston Electric Company.

This case, heard on Saturday in the Queen's Bench Division before Justices Wills and Wright, raised a question as to the right to retain a large sum paid by purchasers under a contract. It was an action brought to recover the sum of £1,000 paid to the defendant Company by the plaintiff Company under a contract for the purchase and delivery of certain electrical machinery and plant which were to be delivered to the plaintiffs at Liverpool from the defendants' factory in America. The terms of the contract contained in letters of May last were that the defendants were to deliver at certain prices (over £6,000) the electrical machinery specified "on ship's rail at Liverpool," the goods to be shipped from America by June 13th last. The plaintiffs were to pay for the apparatus and machinery £1,000 with the order confirming the contract and 33 per cent. on the invoiced amount on delivery of bill of lading and the rest on starting of the apparatus. The £1,000 was sent by the plaintiffs (the purchasers) with their confirmation of the order, and certain apparatus and material were shipped and the bill of lading sent, but the sellers stopped the goods as the 33 per cent. was not sent on delivery of the bill of lading, and the purchasers now sued for the recovery of the £1,000, which the sellers resisted on the ground that it was a deposit or "earnest" and forfeited by the breach of the contract. The plaintiffs claimed to have summary judgment under Order XIV., but there was a counter-claim by the defendants, and an order was made at Chambers giving the defendants unconditional leave to defend, against which the plaintiff Company appealed.

Digitized by Google

Counsel having been heard on both sides, the learned Judges conferred, and Mr. Justice WILLS said he came to the conclusion that the order at Chambers was right. He did not think that Order XIV., providing for summary judgment, applied to cases like this, raising what might turn out to be a difficult question of law. It was never intended to throw on the Judge at Chambers such a burden. It was impossible that such questions could be satisfactorily dealt with at Chambers. This very case had been so argued as to occupy about two hours, and yet no time was wasted. Such questions were not meant to be dealt with summarily at Chambers. And on that ground alone he should uphold the order, allowing leave to defend. But, on the merits, he was not satisfied that the defendants—the sellers—were not entitled to retain the £1,000. When the plaintiffs—the purchasers—renewed the bill of lading, they had not remitted the amount due under the contract, and, though they had properly returned the bill of lading, the sellers might contend that they were entitled to retain the money. He certainly was not satisfied that the defendants were not entitled to retain the money. At all events, it was far too disputable a question to be decided summarily. To decide such cases satisfactorily at Chambers was not possible, and it only tended to put the Judge at Chambers in a false position. Further, in the present case, there was a substantial counter claim. The order, therefore, made at Chambers was right.

Mr. Justice WRIGHT was of the same opinion. It was not shown that the defendants had not from the first conceived that they had right to retain the £1,000, making, as they did, a claim for substantial damages.

The appeal was therefore dismissed and the order upheld.

Hoerter and Another v. Hanover Caoutchouc Gutta-Percha and Telegraph Works.

This case was heard in the Court of Appeal on Monday, before the Master of the Rolls and Lords Justices Lopes and Kay, and was an appeal from the Divisional Court refusing to set aside the writ of summons and service of the notice thereof on the defendants. The plaintiffs, who carried on business in London as C. F. Mumm, brought this action for commission on the sale of goods, as agents for the defendants, who were a foreign company carrying on business at Linden, near Hanover, and for an account. By a contract in writing made at Linden, in the German language, on June 21, 1890, as modified by another contract of December 4, 1891, the defendants appointed the plaintiffs, who were described as trading as C. F. Mumm, of London, their sole agents for the sale of their goods in the United Kingdom, Canada, and the United States of America until October 1, 1892, the plaintiffs to receive a commission of 5 per cent. "upon all net amounts of invoices received after deducting freight, duty, and packing," on all sales by them of the defendants' goods. The commission was to be accounted for quarterly, and the collection of the amounts of the invoices was to be made by the defendants alone. The contract further provided that in case of disputes the plaintiffs' firm was to submit to the laws and jurisdiction in force in Hanover. On February 27, 1893, the plaintiffs issued an ordinary writ against the defendants for service within the jurisdiction, and the writ was served upon one Gilbert, on the ground that he was an officer of the defendants, who had a place of business and carried on business within the jurisdiction. The defendants entered a conditional appearance, and on March 20th the Master, on the application of the defendants, set aside the service of the writ on the ground that the defendants had no place of business here, and that Gilbert was a mere agent of the defendants. On May 2nd the plaintiffs applied *ex parte* to Mr. Justice Mathew, at Chambers, and he gave them leave to amend the writ by making it a writ for service out of the jurisdiction, and to serve notice thereof on the defendants out of the jurisdiction. Notice of the amended writ was accordingly served on the defendants abroad, and they entered a conditional appearance, and applied at Chambers to set aside the writ and all subsequent proceedings. Mr. Justice Wills set aside the notice of the writ and service thereof, upon the ground that the contract provided for the determination of disputes between the parties by the Courts of Hanover. The Divisional Court discharged this order, upon the ground that there was a breach of contract within the jurisdiction—namely, non-payment of the commission, and that the clause in the contract did not give the Courts of Hanover exclusive jurisdiction. The defendants now appealed, and counsel were heard on their behalf, but their Lordships, without calling on the plaintiffs' counsel, dismissed the appeal.

The Medical Battery Company (Limited).

At Marlborough-street Police-court, on Wednesday, C. B. Harness, J. M. M'Cully, C. B. Hollier, and Dudley Towers were charged on remand, before Mr. Hannay, with having conspired to defraud; also with having conspired to obtain by false pretences £52. 10s. from Colonel Jeremiah Brasyer, C.B., and other sums from other persons, in each case with intent to defraud.

The depositions which Mr. William Lynd made last week were read over by Mr. Lyell, the chief clerk, and at Mr. Lynd's suggestion the following words were added to them:—"I wish to state that when Mr. Harness said that he did not wish me to advertise Thomson and such cattle he said so in a jocular manner, and with no intention of depreciating that gentleman."

Mr. LYND was then further cross-examined by Mr. Avory: Every allusion in the lectures to Harness and to his appliances was discussed and dictated to him at a meeting held at No. 52, Oxford-street. After he delivered the lectures he did not, to the best of his belief, ask Mr. Harness to give him an appointment at the establishment. He should have been very pleased to accept an appointment if Mr. Harness had accepted his conditions. He was very glad when he had finished with the affair. After he had delivered his lectures he did not set up a rival establishment. He did, however, set up an establishment for the treatment of persons by electricity in conjunction with the members of the medical profession. It was called the Electro-Dynamic Medical Institute, and was in Bloomsbury. He was not the proprietor of the concern. He was the electrician to it. From the institute advertisements were issued stating that consultations were free. They were always held in the presence of a medical man.

Mr. AVORY: Perhaps there were not many consultations? The witness: The place was too genuine to be a success.

Continuing, the WITNESS said that electrical belts were sold at the place, the price being from one to two guineas. Only a few belts were sold at the place, which he soon left, as he saw it would not be a success. The material of which the belts were made would cost about 5s. or 6s. The witness made the belts himself. He had heard that Mr. Dale, the proprietor, had got into trouble; that he was tried and convicted at the Old Bailey. He had not seen him since 1887.

Mr. FREDERICK THEOBALD BURBAGE, a provision dealer and grocer at Liphook, Hants, and Mrs. KATE WILCOCKS were then called and repeated the evidence given on the occasion of the arrest of Dudley Towers as to the mode of treatment and payment in force at Mr. Harness's establishment.

Mr. HANNAY remanded the prisoners until Thursday.

THURSDAY, NOVEMBER 30TH

On the hearing of the case being resumed, the first witness called was Mr. T. E. Gatehouse. He said he was editor-in-chief of the *Electrical Review*, and had had 20 years' experience as an electrical engineer. He had taken a great deal of interest in the question of the so-called electropathic belts, and he had written articles with regard to them in the *Electrical Review*. In consequence of these articles the Medical Battery Company brought an action for libel. The libel action was dismissed with costs for want of prosecution, under an order. His firm brought an action against the Medical Battery Company for libel, and the libel complained of was a letter, dated September 16, 1892, sent out to newsagents, alleging that their paper contained libels.

Mr. GATEHOUSE said that Mr. Harness was present in Court when that action was heard, the result of which was that his firm was awarded by the Lord Chief Justice £1,000 damages, and costs. He (Mr. Gatehouse) had examined a great number of belts, which he found absolutely valueless, and nobody with the slightest knowledge of electricity would sell such an article as being of any curative value whatever. An ordinary incandescent lamp of 16 c.p., such as is to be seen alight in the London shops, required an electrical energy of 60 watts to keep it at 16 c.p. To produce this amount of electrical energy by means of the Harness electropathic belts, as worn on the average human body, would require the employment of more than 8,000,000 belts.

Mr. AVORY (for Harness): But they were never advertised as being of 16 c.p. (laughter.)

A number of belts were handed to witness, and he declared that not one of them would give the slightest electrical effect.

After some further evidence the case was adjourned till to-day (Friday).

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 18, 1893.

Incandescent Lamp Litigation.—The Federal Court of Appeals of New York has modified the injunction restraining electric light companies competing in New York City against the Edison Illuminating Company, so far as to require the latter company to furnish lamps at a reasonable price for such buildings lighted by the competing companies prior to the decision of July 14, 1891, sustaining the Edison lamp patent. This, by implication, sustains the general right of a patentee to absolutely refuse to sell a patented article if he so chooses. The Oconto lamp case has been argued on appeal at Milwaukee, and is now in the hands of the Court, which will meet for consultation on November 30th.

The American Institute of Electrical Engineers.—At the meeting of the Institute, on Wednesday, November 15th, a scheme was finally adopted providing for local meetings. Upon the application of not less than twenty members residing in any stated locality, the Council shall authorise the holding of local meetings in that locality, and appoint a local honorary secretary residing there. Such meetings shall be for the purpose of reading, by the author or by proxy, and discussing, papers accepted by the Institute, and such papers only. Such local meetings shall be held simultaneously with the Institute meetings, or subsequently, and no papers shall be read or discussed in a local meeting in advance of its reading at the Institute meeting. The local honorary secretary will transmit to the secretary of the Institute a report of the discussion at the local meeting, together with any written discussions or comments on the papers that he may receive from members in his locality. The publication of the discussions in the *Transactions* shall be subject to the regulations and restrictions as govern the discussions of the regular meetings of the Institute. No publication of papers or discussions at local meetings, in local or other journals or newspapers, will be permitted without the sanction of the Council or the secretary of the Institute.

CORRESPONDENCE.

DEFINITION OF ELECTROSTATIC POTENTIAL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I venture to call attention to the definitions of Electrostatic Potential found in most English text-books, as they appear to me in danger of misleading students with respect to the *dimensions* of potential.

The definitions referred to commence with the statement:—"The potential at a point is the work which would be done on a unit of positive electricity," &c. The student might thus suppose it to be implied (by the words "*is the work*") that potential is of the dimensions of *work*, whereas, of course, it is of the dimensions of *work divided by quantity of electricity*. Would it not, therefore, be preferable to define potential as a particular ratio, somewhat as follows?

Suggested definition of Potential.—Suppose an indefinitely small body to carry a quantity, Q, of positive electricity, and let W denote the work done by the electric forces upon this body when it moves from any point, P, to an infinite distance. *Then the electrostatic potential at the point P is the ultimate value of the ratio W/Q* in the limit where Q is so small as not to disturb the electric distribution due to the other charges in the field.

Possibly an objection similar to that just urged against the definition of potential might apply in the case of definitions of other quantities, but I now mention potential as that is the one whose definition first struck me as capable of improvement.

The importance of a correct knowledge of the dimensions of physical quantities is now being very strongly insisted upon. It therefore seems to me highly desirable to avoid, as far as possible, all risk of being misunderstood in this respect, at any rate in the *definitions* in *scientific* books, even though, for brevity's sake, a little looseness of expression may be tolerated elsewhere.—Yours, &c., EDWIN H. BARTON.

Nottingham, November, 1893.

TESTS OF GAS BURNERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In connection with your reference in the last issue of *The Electrician* to corrections for variations of atmospheric pressure and temperature in reducing photometric tests of gas-burners, we venture to submit the following considerations:—

(1) The illuminating power of gas is not so much affected by the temperature of the air surrounding the burner as by that of the gasometer, mains, &c., through which the gas passes. The temperature of the flame is of the order of 1,000°C., and the variation in the heat expended in warming the air used for combustion up to that temperature is not a big item in the thermal balance-sheet for ordinary variations of temperature. In "regenerative" burners, where the air or gas, or both, are warmed some hundreds of degrees, the efficiency is considerably altered, as seen in the Wenham and other burners of this character.

On the other hand, it is well known that the illuminating power of coal gas depends mainly on the percentage of volatile hydro-carbons, chiefly benzol and naphthalene. These are condensed in the mains and pipes exposed to cold, and the illuminating power is thus impaired. It is also an important fact that water largely dissolves out these constituents. We have found that coal gas if passed into a gas bag loses a considerable percentage of these illuminants, apparently by condensation on the sides of the bag; and not until the bag has been many times emptied and refilled does this deterioration cease. Hence it would appear that a correction for temperature is practically an analysis of the gas reaching the burner, as the effects will depend on diameter, length, and exposure of mains, &c., and can hardly be reduced to a simple factor.

It is highly probable that the Welsbach incandescent burner and the albo-carbon ones are very little affected by change of temperature, while the regenerative gas burners would be almost equally affected with those burning cold air. Similarly one would expect the pentane and amyl-acetate lamps to be little affected, though the temperatures are rather lower than those of gas burners. We can find no record of tests to ascertain this somewhat important point in the report of the B.A. Light Standards Committee.

It is worth noting that the density of gas will vary some 10 per cent. with changes of temperature.

(2) With regard to pressure. A variation of 3in. in the barometer changes the mass of gas in a cubic foot by 10 per cent. but in photometric tests, where a gas standard is used, one would expect the standard to vary as much as the burner under test, and keep the ratio unaltered. Indeed, it is probable that all flame sources of light are affected. An alcohol flame is brightly luminous under four atmospheres pressure, and in Mr. Vernon Harcourt's tests of his pentane standard it was found that 1in. increase in barometric pressure required the height of the flame to be reduced about 3 per cent. to keep the light constant (B.A. Reports,'85). No details are given, however, as to what standard was used in these tests, and it appears very difficult to investigate the matter as long as we have no reliable standard other than a flame one. If incandescent, arc, and platinum standards are all to fail us, the pentane and gas standards will be able to vary considerably with atmospheric pressure without much risk of being found out.—Yours, &c.,

City and Guilds of London Institute, Exhibition Road, London, S.W. — H. C. HAYCRAFT, C. A. GAWTHORP.

November 28, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, which has a special interest at the present time, is now ready, and will be forwarded on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus can be obtained on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready, and will be sent direct on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus will be forwarded free on application.

TENDERS INVITED.—The Vestry of St. Pancras invite tenders for excavating and constructing an underground water tank in connection with the electric lighting and refuse destructor station in King's-road, Camden Town, London, N.W. Drawings can be seen at the offices of Prof. H. Robinson, C.E., 13, Victoria-street, London, S.W., where copies of conditions, &c., can also be obtained. Tenders must be sent in to Mr. Albert E. Pycraft, chief clerk, before 12 o'clock on Friday, December 8th. Further particulars are given in our advertisement columns.

———— The Town Commissioners of Fermoy, Ireland, invite proposals and specifications for lighting the town by electricity for twelve months, or such longer period as may be agreed upon. Some further particulars will be found in our advertising columns, and other information can be obtained of Mr. P. J. Lane, Town Clerk's Offices, Fermoy, co. Cork.

———— Tenders are required for fitting up the electric light in a small steam yacht. Applications to be sent to Messrs. J. and H. M. Paterson, 32, Eldon-street, Greenock.

TENDERS ACCEPTED.—The Halifax Corporation have accepted the following tenders in connection with their central station in Cripplegate:—Engines, Messrs. Pollit and Wigzell, Sowerby Bridge; boilers, Messrs. Yates and Thorn, Blackburn; and mains, Messrs. Siemens Bros. and Co. (Limited), London.

TENDERS RECEIVED.—At the meeting of the Sunderland Corporation Highways Committee on Friday a sub-committee presented a report on the tenders which have been received from contractors to lay the necessary plant for the introduction of the electric light in the main streets of the town. There were eight different contracts tendered for, as follows:—(1) For Lancashire boilers, 28 tenders, prices varying from £1,235 to £2,500; (2) engines and dynamos, 16 tenders, prices from £4,640 to £6,015; (3) motors and alternative switchboards, 15 tenders, prices from £1,100 to £3,000; (4) main switchboard instruments and connections, 19 tenders, prices from £575 to £1,350; (5) batteries, seven tenders, prices from £763 to £2,260; (6) installation couples, seven tenders, total prices to be ascertained on measurement; (7) roadwork, prices to be ascertained on measurement; (8) copper strip, 11 tenders,

Digitized by Google

prices from 5⅝d. to 7½d. per pound. One firm, Messrs. C. A. Parsons and Co., of Newcastle, tendered for the whole of the work for £19,044. The differences between the amounts for the various contracts decided the Committee on sending the whole of the tenders to Prof. A. B. W. Kennedy, their consulting engineer, who will go through them and report on them.

Sale of Stores.—Mr. Charles E. Stuart, Controller of Stores, announces that by command of the Postmaster-General tenders are invited for the purchase of about 30 tons of gutta-percha in various forms, old india-rubber, old copper, and other metals, mercury deposit, ebonite, &c., &c., all arranged in convenient lots. Forms of tender, containing all particulars, can be obtained of Mr. Charles E. Stuart, Controller of Stores, General Post Office, Telegraph-street, London, E.C., and tenders must be sent in by noon on Thursday, December 14th. Further particulars are given in our advertisement columns.

Appointments Vacant.—The Manchester Corporation Gas Department require a thoroughly practical and experienced foreman, accustomed to dealing with workmen and competent to undertake all classes of cable work, &c. A permanent position is offered to a good man. The Department also requires several good vulcanised rubber curers and jointers, as well as a meter inspector and tester. Written applications for these appointments must be sent in to the Chairman of the Gas Committee, Town Hall, Manchester. Further particulars are given elsewhere.

Change of Address.—Messrs. Tickner and Partington, art metal manufacturers and electric light contractors, have removed their offices to their manufacturing premises, Vulcan Works, Kensal Rise, London, N.W.

———— Messrs. Marryatt, Lillywhite and Co. announce that their only address is now 57D, Hatton-garden, E.C.

Fire.—On Saturday last the old factory of the Zurich Incandescence Lamp Company at Birmensdorf, Zurich, was almost entirely destroyed by fire. The fire was discovered about 3:30 a.m., and the alarm at once given by the watchman on the premises, and in response to his call the village fire brigade promptly arrived, followed by those of the surrounding villages, and owing to their exertions the new factory, which was nearly completed, escaped with only very slight damage; the books of the Company and a part of the stock were also saved. As the Zurich Company have, in addition to the stock saved from the fire, large depots of lamps in various European centres, it is expected that deliveries of existing orders will be resumed in a few days, and that the interruption to the manufacture will be of very brief duration. We learn that the loss is fully covered by insurance.

Venus Glow Lamps.—Mr. G. Straus, the sole representative of the Hamburg Incandescent Lamp Company in this country, is removing from the temporary premises at 158, Strand, W.C., to larger offices and show rooms at 130, Queen Victoria-street, E.C.

Messrs. Redpath and Paris.—This firm send us their new illustrated catalogue of patent high-speed noiseless engines—simple, compound, or triple expansion, condensing or non-condensing—for which a claim is made that they are specially adapted for driving dynamos for electric lighting or other high-speed machinery.

Mr. Fernand Espir.—We last week announced that Mr. Espir had been appointed sole agent for Great Britain and the Colonies for Messrs. Lazare Weiller and Co.'s specialities, and we are requested to state that stocks are to be kept in London, so that prompt delivery may be ensured.

Standard Electrical Time-Recording Company (Limited).—This Company are exhibiting some new time-recording instruments which have just been introduced into this country. By the Company's system, time-recorders to any number can be governed by a self-contained installation, and every station clock upon the greatest railway system in the world can be controlled, or a few clocks in a country house can be kept uniformly correct by a simple battery. The receivers are placed in circuit with the regulator clocks, and there is only one contact for the entire circuit. This contact is of short duration, being only one-eighth of a second; but the working of all the receivers within the circuit is perfect and their synchronisation absolute. By a special arrangement, the movement of the hands of all the receivers takes place before the complete break of the current in the regulator. The contact is made in the regulator clock every half-minute, the current winding up the main spring simultaneously. From a single regulator clock any number of receiver dials can be worked.

"Constantinople in London."—Messrs. Benham and Froud (Limited), of the Chandos Metal Works, Chandos-street, London, W.C., are making for the exhibition of Constantinople in London a number of large handsome brass domes, perforated and lined with ruby, and with outer brass work, to carry the arc lamps for the electric light, as well as a large number of copper, brass, and wrought-iron lanterns for the incandescent lighting of the streets, bridges, &c., in the exhibition, from original Moorish designs by Mr. R. W. Laws, who is superintending their manufacture.

Chelmsford.—The Town Council on Wednesday referred to a Committee of the whole Council the consideration of the offer of Messrs. Crompton and Co. (Limited) to renew the contract for lighting the town by electricity and of the draft Provisional Order which the Company are endeavouring to obtain from the Board of Trade.

Dolgelly.—The electric-light installation has not been giving satisfaction lately, the whole of the town not having been lit at one time for some while, and the Local Board have had the subject under consideration at two or three meetings. At a meeting on the 13th inst., after a long discussion, the Authority resolved to communicate with Messrs. Hall and Co., asking whether they had any proposals to make before the Board made other arrangements, and also to inquire of the Gas Company their terms for lighting the town. At the meeting held last week Messrs. Hall and Co. wrote that the lighting would henceforth be satisfactory, as they now had plenty of coal, the scarcity of which was the cause of the previous failure to light the town. The Board, however, postponed a final decision on the matter.

Electricity and the Price of Gas.—The price of gas at Aberdare has been 4s. 3d., but an electric light company having intimated that they were about to apply for a Provisional Order the price has been reduced by 3d.

Galashiels.—The Caledonian Electric Supply Company having asked the Corporation to consent to their application to the Board of Trade for a Provisional Order, the local Gas Company also wrote to the Council, stating that they were prepared to supply the electric light if there were a demand for it. The Corporation decided to remit both communications to a committee to consider and report upon.

High Wycombe.—The Town Council at their last meeting appointed a Committee to carry out the provisions of the Provisional Order they have applied for.

Huddersfield.—At a meeting of the shareholders of the Huddersfield Industrial Society, on Saturday, the Committee were authorised to light up the premises of the Central Store with electricity. It was stated that the estimated cost would be £1,600, that 550 lights would be put in, and that, considering that the engine and boiler which they proposed to put in would do other work besides supplying motive power to the dynamo, there would be a direct saving (besides a large indirect one) upon the present cost of gas, and an estimated direct saving of nearly 50 per cent. by working their own plant rather than taking electricity from the Corporation.

Ingleton.—A meeting of ratepayers was held on the 16th inst., to consider the question of introducing the electric light. Mr. T. Preece, of Messrs. Andrews and Preece, Limited (not Mr. W. H. Preece, F.R.S., as has been erroneously reported), submitted a scheme which would cost £1,500, exclusive of land, buildings, Parliamentary and other professional and legal expenses. A committee was appointed to consider the scheme and report thereon.

Lectures.—A series of University Extension lectures on electricity is being delivered at Spalding by Mr. W. Cassie.

Mevagissey.—The Lighting Committee submitted to the Vestry at the last meeting estimates for lighting the town by oil, gas, and electricity. They reported in favour of the latter, but recommended that the matter be deferred for the present.

Monmouth.—Mr. Thomas Codrington held an inquiry on behalf of the Local Government Board at the Shire Hall on Friday, respecting a proposed loan of £18,000 by the Corporation for the purpose of carrying out a complete scheme of drainage and electric lighting for the borough.

Pontypool.—Dissatisfaction was expressed at the last meeting of the Local Board with respect to the present lighting of the town by gas, and a Committee was appointed to consider whether better gas lamps should be placed at the more important parts of the town, or whether the Board should adopt the electric light.

Reading.—The temporary electric lighting of the Town Hall, on the occasion of the visit of H.R.H. Princess Christian, to open a Bazaar on the 23rd and 24th inst., was carried out by Messrs. T. C. Williams and Sons, Electrical Engineers, of Reading, by means of 17 high c.p. incandescent lamps, the current for which was supplied by the Reading Electric Supply Company (Limited).

Shanklin.—The Local Board have appointed a Committee to consider the advisability of lighting the town by electricity.

Smoke Abatement.—It is rumoured that Mr. Samuel Elliott, of Newbury, Berks., is about to give the investing public an opportunity of taking an interest in an invention in which Mr. Elliott turns to profitable account the residual products of coal. Mr. Elliott claims that his new invention goes far towards solving the great smoke problem. Interesting experiments have, we understand, been carried out at the Birmingham Mint, and excellent results are stated to have been obtained.

St. Mary, Islington.—The following is the report of the Special Electric Lighting Committee recently appointed to inquire into the

Digitized by Google

subject of electric lighting :—The Committee has made exhaustive inquiries for a site for the proposed electric lighting works, and, as it has had considerable difficulty in finding suitable sites in the parish with the obvious requirements for a central station, its labours have extended over a longer period than was anticipated. The Committee recognised the supreme importance of obtaining a site adjoining one of the lines of railway running through the parish, so that siding accommodation for coal could be provided. It has, therefore, confined its inquiries to sites adjacent to the Great Northern and North London Railways. The Great Northern Railway Company's property in Eden-grove and Burnard-place, Holloway, was brought to the Committee's notice, and its suitability was immediately appreciated. The site is bounded on two sides by the Great Northern Railway. Your Committee has had lengthy negotiations with the Company, and is now informed that the Directors have expressed their willingness to sell the property. The land covers an area of about 32,400 sq. ft., and the sale would include the buildings existing on the same at the present time, the annual rental of which is estimated at £335. The price required for the property would, the Committee understand, be about £8,500. The Company also agree to depart from their usual practice by constructing the proposed siding to the works free of cost to the Vestry. The property is freehold, and is subject only to tenancies, all of which can be determined not later than March 25th next, if required. The site is almost in the centre of the parish, and although of not so large an area as your Committee would desire to secure, is capable of easy development by the acquisition of adjacent property should it be necessary hereafter to extend the works. Its situation makes it most convenient for the supply of electricity to any part of the parish, and considerable saving in the cost of "feeder" mains and in the loss of electrical energy will thereby accrue. Engine rooms can be erected capable of containing at least 11 sets of plant for incandescent lighting (allowing full room for slow-speed horizontal engines), and six sets for arc lighting; ample accommodation will be available for offices, switch room, workshops, coal stores, &c.; and easy means of obtaining coal direct from trucks into the works can be secured. This latter advantage is in fact more important than is at first apparent. For instance, by the end of the third year it is probable that the coal consumption will exceed 4,000 tons per annum. This quantity, if carted in the usual manner, would probably cost not less than £200 per annum for carting alone, which, if capitalised at 3½ per cent. would be equal to an outlay of nearly £6,000. Again, in the site in question, in consequence of the trucks being able to run right into the stoke hole, cost of labour in wheeling coal will be avoided, and a saving of at least £100 per annum for the first three years effected. For some time the three houses known as Nos. 25, 27, and 29, Burnard-place, included in the proposed site, can remain standing, and the rents of these houses (about £80 per annum) would consequently be received by the Vestry so long as the houses remain and their value is not deteriorated. It is possible also that for the present No. 50, Eden-grove (the estimated value of which is £55 per annum), might be allowed to remain, although probably at a reduced rent. Delay in commencing the supply of electricity means the loss of certain large customers who are hesitating to put down their own plant in the anticipation of obtaining an early supply from the Vestry, and even if the work is commenced immediately current will not be available until some twelve months have elapsed. Having regard to all these circumstances, and to the fact that there is no other available site, so far as your Committee is aware, adjoining one of the railways in the parish which would be suitable for the erection of the proposed central station, and also to the fact that there are no other interests to acquire in the property under consideration, the Committee unhesitatingly recommends the Vestry to refer it to the Committee to carry out the negotiations for the purchase of the site upon the terms and conditions named.—At the meeting of the Vestry called to consider the report, Mr. Lambert moved its adoption. The Committee were unanimous in its recommendation. Mr. Vine seconded. In the purchase of the Eden-grove site they would only have to deal with one vendor, whereas in the other sites a number of vendors, leaseholders, and freeholders would have to be considered.—Ultimately 38 voted for, and only 2 against, the adoption of the report.

WEYBRIDGE.—The Weybridge Electric Supply Company have informed the Vestry that they have now received Prof. A. B. W. Kennedy's report as to placing their wires underground, and that it will be immediately considered by the Directors, who hope very shortly to be in a position to state when the wires would be altered.

COMPANIES' MEETINGS.

International Okonite Company (Limited).

An extraordinary general meeting of this Company was held on Saturday at Cannon Street Hotel, Mr. Samuel Pope, Q.C., presiding.

The CHAIRMAN said they were probably aware that the object of the meeting was to confirm, or otherwise, certain resolutions passed at an extraordinary general meeting held about a month ago (and reported in *The Electrician* of November 3rd). It would be within the recollection of some present that when they came to discuss these resolutions they found that the shareholders on the other side of the water commanded, and were represented at the meeting by, so large a preponderance of proxies, that they were practically at their mercy, and whatever view might be entertained by them, the resolutions would be carried if the American votes were given in their favour. But, as the result of the discussion, there were objections taken by various English shareholders to some of the propositions which had been sent from the other side, notably to one for abolishing the power of the Company to purchase its shares, and which would affect their standing on the Stock Exchange. The resolutions were passed on that occasion, but the gentleman who held the American proxies intimated that he would represent to his *clientèle* the feeling which prevailed amongst a considerable bulk of the English shareholders with regard to some of the suggestions. Since that meeting a letter had been received from the other side, saying that, although they themselves remained of opinion that the whole of the resolutions, as submitted, would be for the general interest of the Company, yet that, in deference to the strong feeling on this side, they would modify them to the extent of not interfering with the existing article with regard to the purchase of shares of the Company by the Company itself; therefore the resolutions would be submitted for confirmation minus that particular part which had met with considerable criticism. Speaking for himself, he confessed that, although he did not see how they could avoid confirming the resolutions if they wished, he was by no means dissatisfied with them now that the alteration he had mentioned had been agreed to. His whole interest, with the exception of debentures he had bought from time to time, was in Ordinary shares, and as a holder of such he felt that the best thing that could be done was to pass the scheme embodied in the resolutions before them.

Mr. WILLIAMS moved that the whole of the resolutions be confirmed, with the exception of sub-section A of clause 2, which read as follows:— Rescind article 35 and substitute the following: "The Directors may accept surrenders of shares on such terms as they think fit."

Mr. VAUGHAN STEVENS seconded the motion.

Mr. E. GLADSTONE thought the clauses or resolutions should be put *seriatim*.

The CHAIRMAN said he was quite willing to do so, but it would have no effect, because there was a large block of American shares that would enable them to be carried.

Mr. STEVENS remarked that the capital of the Company was £340,000, and that Mr. Williams had duly lodged proxies in proper order to the value of £165,490 in favour of the resolutions.

The CHAIRMAN said as a Board they had no proxies, and added that the effect of the resolutions was to transfer the management of the Company to America.

Mr. GLADSTONE said he thought they ought to take a poll on the resolutions. The Americans sold their property at ten times its value, and now they were asked to place it at their entire disposal.

The CHAIRMAN replied that that was no doubt the individual opinion of a great many, but the question was how, in the constitution of a company, that individual opinion was to make itself felt. They had heard that they were faced by a solid block of shares equal to about half the capital. In the face of that he felt himself powerless.

Mr. HOPPS said he thought that as the American people had played the game so cleverly they should be compelled to lodge their proxies for every resolution.

The CHAIRMAN said the American business of the Company was making profits, and those interested in it on the other side objected to having those profits taken from them to make up losses on this side. The English Directors had not been able to make the business on this side pay as soon as they had hoped, and they had therefore followed the suggestion of the American Directors and closed the Manchester works. At some future time it might be possible to reopen them; but just now they were depending upon the profits made in the United States. Speaking as an ordinary shareholder, he felt that the only chance he had of getting a dividend lay in the surplus profits of the American business after meeting the expenses there. As to taking a poll, if a requisition were handed him by five shareholders holding one-fifth of the capital he must grant it.

Mr. CLEMENTS, the solicitor for those representing the American block of shares, said that, as those on the other side had given way on the point principally objected to at the last meeting, he hoped there would be no attempt, although it must be useless, to defeat the resolutions.

Mr. GRIFFITH said he thought the policy they were asked to adopt was one that must commend itself to thinking minds. The one question that arose in his mind was whether it would not be wise to sell their magnificent works at Manchester, and so bring money into the coffers of the Company.

Mr. CLEMENTS replied that it was the intention of those responsible to wait until better times, and, if it should then be possible to resume business at Manchester profitably, to do so.

The resolutions were eventually confirmed, and the proceedings concluded with a vote of thanks to the Chairman.

Elmore's French Patent Copper Depositing Company (Limited).

Mr. C. J. Stewart (Official Receiver and Provisional Liquidator) on Tuesday last issued his summary of the affairs of this Company.

Mr. Stewart says the Company was incorporated September 10, 1890, for the purpose of acquiring and working in France certain French patents relating to an improved process for manufacturing copper articles, "discovered" by Messrs. F. E. and A. S. Elmore, and patented by them in or about the year 1885. In 1889 a company was formed to acquire and work their patents relating to Great Britain and Ireland. At the date of the formation of the French Company Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited) (referred to hereafter as the Foreign and Colonial Company) were the owners of all the existing patents for other parts of the world than Great Britain and Ireland relating to the Elmore copper process. On September 4, 1890, the Foreign and Colonial Company agreed with Woodhouse and Rawson United (Limited) that the latter should form a company for the purpose of acquiring the patents for France in consideration of £15,000 in cash, the whole of a premium of 10s. on each of 51,750 shares if subscribed for by the public, and half of a like premium on any further number of shares allotted to the public. The benefit of this agreement was transferred by Woodhouse and Rawson United (Limited), on September 9, 1890, to the Phœnix Trust Company (Limited), which company appears to have actually promoted the French Elmore Company. On September 10, 1890, the French Elmore Company agreed to purchase from the Foreign and Colonial Company the French patents for £83,500 in cash, £66,500 in the form of 33,250 £2 shares credited as fully paid up, and the premium of 10s. on each share subscribed for by the public. This agreement was duly carried out; the purchase price paid to the vendor company was £183,375, of which £66,500 was in shares and £116,875 in cash. A prospectus was issued to the public in September, 1890, containing extracts from various reports speaking in favourable terms of the Elmore copper process, and the whole of the original capital of £66,750 offered to the public was at once subscribed for, and was allotted on September 19 and September 22, 1890. Mr. F. L. Rawson, a Director of the Foreign and Colonial Elmore Company, of Woodhouse and Rawson United, and of the Phœnix Trust (though not a Director of the Elmore's French Company), appears to have frequently attended the French Company's Board meetings, and to have exercised great influence in the management of the affairs of the Company. In order to meet increased outlay owing to various undertakings entered into by the Company, an agreement was made on October 29, 1890, with the Foreign and Colonial Elmore Company to issue debenture stock for £50,000 at 6 per cent., redeemable at £105 on November 1, 1893. In pursuance of this agreement, the Foreign and Colonial Company appears to have advanced £50,000 to the Company in various sums as required. The debenture stock for the most part seems to have been taken up by the shareholders of the Foreign and Colonial Company. The payment for all expenditure in France, including the cost of the erection of the buildings and the machinery at Dives, was in the hands of M. Secrétan and the Paris committee, who drew upon the Company's bankers in France, the latter being supplied from time to time with funds from the London bank of the Company. No accounts in detail of such expenditure appear to have been furnished to the Board in England, but the books in France were audited annually by Messrs. Deloitte, Dever, Griffiths and Co., the Company's auditors, and a summary of the assets and expenditure in France was supplied to the Board, and included in the annual balance sheets. The Directors seem to have disregarded the suggestion of the auditors that the total of the cash-book expenditure should be initialled by M. Secrétan as an indication of his approval of the payments made. It was stated by M. Secrétan at the first general meeting of the shareholders, on January 9, 1891, that works constructed to produce 370 tons of copper articles per month would commence manufacturing on July 1, 1891, and would, at the end of three months, have reached their full production. In consequence, as it is represented, of defects in the soil on which the works were being constructed, and of the difficulty in finding suitable machinery for working the Elmore copper process, which necessitated a considerable expenditure of time and money in experiments, in order to discover such machinery, the cost of the works largely exceeded the original estimate, and the manufacture of copper articles for sale does not seem to have commenced until April, 1892, between which date and December 31, 1892, the total sale of such articles was under 100 tons. At a general meeting of shareholders on April 22, 1892, it was decided to increase the capital of the Company by the creation of 100,000 Preference shares of £2 each, to be entitled to a priority on a distribution of assets, and to a preferential dividend of 10 per cent., and to a further dividend of 5 per cent. after a dividend of 15 per cent. should have been paid on the Ordinary shares. In pursuance of this resolution a prospectus was issued on April 23, 1892, offering 60,000 such shares for subscription, of which 40,000 were reserved for the holders of Ordinary shares of the Company and 20,000 were offered to the public. The same prospectus stated that the interest of 10 per cent. was guaranteed for one year by the Foreign and Colonial Company. On July 16, 1892, of the issue of 60,000 shares, only 13,250 had been applied for and allotted, and on that day another prospectus was issued, offering for subscription on the same terms 20,500 Preference shares, forming part of the 60,000 shares, and on November 19, 1892, a circular was sent to the shareholders in the Elmore Companies offering 10,000 Preference shares on the same terms. The total number of Preference shares allotted is 22,516, on which £44,707 has been paid, and £325 remains due on unpaid calls. At a general meeting of the debenture stock-holders on February 20, 1893, the Directors were empowered to issue new debenture stock to the amount of £100,000, bearing interest at the rate of 7 per cent. Circulars were

Digitized by Google

accordingly issued stating that it was proposed to extinguish the existing debenture stock of £50,000 by conversion or redemption, and offering for subscription £65,000 of the new issue. It was also stated in the circulars that unless £30,000 of the new debenture stock should be subscribed for in cash at par within two months no allotment should be made. The secretary states that applications were received for only £8,533, on which £2,747. 8s. was paid. This amount was placed to a separate account at Martin's Bank, and has not been returned in the statement of affairs, an injunction having been granted by the High Court restraining Martin's Bank from parting with the same. The applicants for the stock are apparently entitled to a return of the moneys. The whole of the Company's monetary resources were exhausted in connection with the establishment of the works in France, and it was unable to meet the interest falling due upon the debenture stock on November 1 1892; under the powers contained in the debentures, Mr. J. H. Duncan was appointed as receiver on behalf of the holders thereof on March 28, 1893, his appointment being confirmed by the Court on April 14, 1893. The Company being unable to continue its business, an extraordinary general meeting of the shareholders was held on May 8, 1893, when it was resolved that the Company should be wound up voluntarily, with Mr. F. W. Pixley as liquidator. On the same day, at an ordinary annual general meeting of shareholders, a resolution was passed approving of an agreement, dated April 29, 1893, by which Mr. Duncan, as receiver for the debenture holders, agreed to sell to M. Secrétan the Company's works, patents, and business in France, the land at Bellegarde being excepted. The sale is now in course of completion. No dividends have been paid on the Ordinary shares. The dividend of 10 per cent. on the Preference shares, which was guaranteed for one year by the Foreign and Colonial Company, appears to have been paid by that Company. Among the unsecured creditors are included four Directors, whose claims in respect of fees amount to £798. 7s. 8d. The claims of the creditors partly secured (£76,081. 19s. 7d.) include one of £27,000 by three persons who hold as security £11,900 debenture stock of the Company, and collateral security of the Foreign and Colonial Company; they appear to have advanced £23,000 to the Company in December, 1892, and received the Company's acceptances for £27,000, payable at intervals until February, 1894, the balance of £4,000 being charged as interest at an average rate of 18 per cent. There is also included a claim of Elmore's American and Canadian Patent Copper Depositing Company (Limited) for cash lent to the Company between October, 1892, and February, 1893, amounting to £7,261. 17s. 4d., to secure which it holds a first charge for £2,000 upon the whole of the Company's property, in addition to collateral security of the Foreign and Colonial Company. The other creditor partly secured is the Foreign and Colonial Company, which holds a mortgage registered in France upon the whole of the Company's property for £95,000 (subject only to the charge of £2,000 above mentioned), the first £50,000 of which is held in trust for the debenture holders. The sum now due in respect of advances upon this mortgage, over and above the amount so held in trust, is returned as £41,784. Of the £50,000 debenture stock issued as before mentioned, in pursuance of the resolution of October 29, 1890, £12,000 appears to have been redeemed by the Company in December, 1893, of which £100 was cancelled and £11,900 transferred as collateral security to the three partly-secured creditors, as before stated. The liability upon debenture stock is thus £49,900, with interest due thereon to the amount of £2,360. 15s. 5d. Some difficulty has been experienced in investigating the Company's transactions with respect to bills, which have been of considerable magnitude. One bill-book has been used in common by all the Elmore Companies, and the Official Receiver has not been able to obtain possession of it. The correspondence, also, of all the Elmore Companies has been kept on a common file. No seal register was kept by the Company.

A summary of the general financial position of the Company is appended to Mr. Stewart's report, which is very voluminous and gives evidence of much labour and research.

Some severe strictures passed by the Press upon the methods adopted by the management of the Company, has drawn from the Secretary (Mr. W. Shurmur) an announcement to the effect that a "scheme of arrangement whereby the Company is to come out of liquidation and to be resuscitated" is under consideration. He concludes:—"I must not now forestall what will probably be announced on this subject at the meeting on the 5th proximo, except to the extent of saying that such scheme, if carried out—about which I have no doubt whatever—will not only satisfy the debenture holders and the unsecured creditors, but will also provide for an annual dividend of 10 per cent. on the Preference shares, and an annual dividend of, probably, 4 per cent. or 5 per cent. on the par value of the Ordinary shares. If there was ground for hope in April last, then that ground has become infinitely stronger now, by reason of what we know is being done at Dives to-day."

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "The Electrician" Electrical Trades' Directory and Handbook, 1893, pages 320-348, &c., &c.]

FARRINGDON WORKS (LIMITED).—This Company was registered on November 23rd, with a capital of £40,000, in £10 shares, to carry on the business of engineers, iron founders, brass founders, millwrights, steam engine and boiler makers, machinists, copper smelters, antimony smelters, metal workers, white lead makers, &c.

GAS TRACTION COMPANY (LIMITED).—This Company has been formed with a capital of £100,000, in £1 shares, to purchase certain patented inventions relating to the traction of vehicles by means of gas, and the objects further include the carrying on of the business of gas engine makers, manufacturers of all kinds of apparatus connected with the generation, storage, compression, supply, application and distribution of gas and electricity, gas, electrical and mechanical engineers, &c. J. Fletcher Moulton, Q.C., one of the vendors, has accepted a seat on the Board.

NEW QUAY GAS COMPANY (LIMITED).—Capital £10,500, in £1 shares. Although this concern has been formed primarily for the purpose of supplying New Quay, a township in Cornwall, with gas, powers are retained for the carrying on of the business of an Electric Light, Heat and Power Supply Company, should that step be deemed by the Directorate to be advisable.

PAYTA TO PUIRA RAILWAY (LIMITED).—This Company was registered on November 23rd, with a capital of £100,000, in £1 shares, to acquire and deal with an important concession relating to the construction, maintenance and working of railways, tramways, telegraphs, telephones, and other means of communication in certain parts of the Republic of Peru.

SMOKELESS HEAT AND LIGHT SYNDICATE (LIMITED).—This Company was registered on November 24th, with a capital of £20,000, in £1 shares, to acquire certain inventions relating to improvements in the production of heat and light for which patents have been granted in most of the more important countries, and to develop and deal with the same.

ELECTRIC ANTI-CORROSION COMPANY (LIMITED).—The solicitors to this Company state that no business has ever been carried on, and its removal from the Register is requested.

ELECTRICAL COAL-CUTTING CONTRACT CORPORATION) LIMITED).—The first annual return of this Company, made up to November 6th, has been filed. The nominal capital is £402,000, divided into 60,000 Ordinary shares of £5 each, 20,000 Deferred shares of £5 each, and 2,000 Founders' shares of £1 each. 9,531 Ordinary, 20,000 Deferred, and 2,000 Founders' shares have been taken up, of which all the Deferred and 4,000 Ordinary have been issued as fully paid. The full amounts have been called on 4,082 Ordinary and the Founders' shares, while a call of £3. 15s. per share has been made upon the remaining 1,449 Ordinary shares. The calls paid amount to £26,563. 15s., leaving £1,280 in arrears.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The Directors of this Company have declared an interim dividend of 3s. per share (at the rate of 6 per cent. per annum) free of income tax, for the quarter ended September 30th last, and payable on December 21st. The transfer books of the Company will be closed from December 14th to 20th inclusive.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended November 26th were £895, as against £893 for the corresponding period of last year, being an increase of £2. The total receipts for the half-year amount to £17,320, against £17,137 in the corresponding period of 1892, being an increase of £183.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce that telegraphic communication has been established between the Company's station at Lisbon and the island of Graciosa in the Azores. The following islands in the Azores are also open for telegraphic traffic:—San Miguel, Terceira, San Jorge, Pico and Fayal. Messages are accepted by this Company at the rate of 10d. per word.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—Notice is given that a drawing of the Six per Cent. Second Mortgage Debentures (to be paid off on January 1st next) will take place at the registered offices of the Electric and General Investment Company (Limited), the trustees for the debentures, 1 and 2, Great Winchester-street, London, E.C., on Friday, December 8th, at three o'clock.

KELVINSIDE ELECTRICITY COMPANY (LIMITED).—The Directors of this Company have issued a prospectus during the past week, inviting subscriptions for £10,000 in Five per Cent. Debentures, redeemable at the option of the Directors, at 20 per cent. premium, any time prior to November 11, 1898, and with the right of conversion into Ordinary shares at the option of the holders any time after the latter date. The Managing Director of the Company is Mr. J. M. V. Money-Kent, of Connaught Mansions, 34, Victoria-street, S.W., and the trustees for the debenture holders are Lord Kelvin, Sir John N. Cuthbertson, and Sir Renny Watson. Dr. J. T. Bottomley, F.R.S., is consulting electrician, and Mr. J. M. M. Munro is electrical engineer to the Company, which was incorporated in 1889, and whose first installation is now nearly completed, and will ultimately cost about £20,000, £17,000 of which has already been expended in buildings, machinery, plant and mains. The central station is designed and built for three times the plant at present installed. The offices of the Company are at 28, Renfield-street, Glasgow, and Mr. W. H. Watson is secretary.

PANULCILLO COPPER COMPANY.—At an extraordinary meeting of this Company, held at Winchester House, E.C., on Friday last week, Sir John Pender, G.C.M.G., M.P., said that the Directors had been disappointed at the very small support they had received from the shareholders in connection with the continuation of the working of the Panulcillo Mine. If those who still held an interest in the mine would go into the new scheme proposed by the Directorate he thought there was still a very good prospect of recouping themselves. The mine had been closed since June 20th owing to want of funds. The present meeting was called to consider an arrangement by which it was proposed to transfer the undertaking to a new company for £22,000, andthe Directors urged the acceptance of this

Digitized by Google

scheme upon the shareholders. The prospectus will be issued early next month, and will only be kept open for subscription for a few hours. The motion proposed by the Chairman was adopted, and a further resolution to wind up the Company voluntarily was also passed.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ending November 24, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited) were £3,379.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 812.—Vol. XXXII. FRIDAY, DECEMBER 8, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6.*

NOTES.

The decision of the City Commissioners of Sewers to remove the gas standards from the streets lighted by the City of London Company's arcs, is, as was said at the meeting "the legitimate outcome of the report of the Engineer on electric lighting." When the percentage of failures in lamp hours has been brought down to 0·047, it is certainly no very rash step to remove lamp-posts, which cost nearly £1,200 a year to maintain, and consume only twenty-eight pennyworths of gas per annum. At the same time, the gentleman who urged further delay, and remarked that the City would be "in a dreadful state" *if* the light failed, need not be scoffed at. We can only trust that the record of the City lighting during the dark days now upon us will be such as to give the public entire confidence in the reliability of electric street lighting when carried out in a workmanlike fashion.

Judging from the graphic account given by a correspondent of the *Standard* yesterday, the hygienic value of the Hermite process of sanitation is one of considerable importance. The deodorising and bacillus-slaying propensities of electrolysed salt water appear to be both prompt and perfect. From the experiments now being carried out at Lorient, it would appear that the worst kinds of sewage may be allowed, after passage through the Hermite syphon, to flow in an open drain along the public street with every appearance of being a limpid and colourless stream of pure water. It is also stated that some of the fever dens of Lorient have been appreciably improved by an application to them of this electrolytic process. It seems that there are two classes of bacillus, those which like oxygen and those which do not like it; but neither of these classes appears to like electrolysed sea water.

The mystery which, notwithstanding the extensive and deep researches of Ewing into the subject, still surrounds the behaviour of the molecules in a mass of iron placed in a varying magnetic field, is very strikingly exemplified by the apparently anomalous results obtained by Mr. S. J. Lochner in his researches on the elongation produced in soft iron by magnetism. Some account of Mr. Lochner's experiments is given in another column this week. A sample of soft bar iron was subjected to a gradually increasing magnetising force, and was found to increase in length up to a certain point. Beyond that point an increase of magnetising force produced actual decrease of length of the bar; while, remarkable to relate, a decrease of the magnetising force caused the bar to continue to grow longer. Further than this, the amount of elongation of the bar in any field was found to depend on the way in which the bar was subjected to the magnetising force, as to whether the force was applied suddenly or gradually, and whether the final strength of field was attained by increase from a lower or by decrease from a higher value. This latter might have been predicted from Ewing's results, for a bar of unmagnetised iron is a disorderly collection of an immense number of molecules; and it might be expected that a very great variety of arrangements of these molecules might each and all correspond to the same intensity of magnetisation, while each would give a different alteration in the length of the bar.

The existence of a critical point in the elongation of the bar, under increasing magnetising force, would seem to point to the existence of two opposing tendencies to change of length. What are the precise causes of this critical point and of the apparent anomaly in the behaviour of the iron can only be settled by very carefully arranged experiments; but we may call attention to the existence of two well defined phenomena in a magnetised iron bar, which may throw some light on this obscure action. It has long been recognised that the rotation of the iron molecules on their axes may account for the increase in length of the bar. On the other hand, the mutual attractions between the adjacent molecular poles would tend to shorten their centre distances. The two effects would occur simultaneously, but it is evident that the former would produce the greater effect at first, while the latter would become more marked when the iron approached a higher degree of magnetisation.

A very high tribute of praise was accorded to Prof. Hertz and his researches by the President of the Royal Society, at the anniversary meeting of that Society last Thursday week. Lord Kelvin, in the opening part of his speech, referred to the recent publication of these researches in the original German, as well as in an English translation by Prof. D. E. Jones. The value of these researches as an experimental contribution to the ether theory of electro-magnetism is universally admitted. In order to give some idea of the position which this theory takes in the evolution of ideas about force and matter, Lord Kelvin sketched the successive hypotheses which have been considered orthodox from the time of Newton to the present day. Sketches of this sort

Digitized by Google

always make one inclined to wonder if the particular hypothesis which happens to be orthodox at the moment may not, after all, be as chimerical as its predecessors. This is the nightmare of science; and when we have shaken it off with a gasp, we try to comfort ourselves with the thought that none of our predecessors followed the "true scientific method" as we moderns do! Descartes, Newton, Boscovitch, Maxwell, and the rest may spin theories; but only in the experimental evidences of a Faraday and a Hertz have we something which looks like solid rock.

Some of the difficulties in the design of arc lamps which are enumerated by Mr. W. A. Turbayne, in his article which we publish this week, are undoubtedly of importance; the others are rather trite. It is the fashion to say that the mechanism of arc lamps has been neglected; but, while this would have been true a year ago, it is not by any means true now, at any rate, as regards English lamps. During the last twelve months considerable attention has been given to arc lamps, both by makers, in regard to their mechanism, and by physicists, in regard to the distribution of light and the relation between watts, volts and carbons. However, it is quite true, as Mr. Turbayne points out, that there are still some important difficulties in the way of making a perfect lamp. But it is by no means clear how any of these difficulties are to be got over, in the case of running lamps in series, by a return to the old-fashioned series-coil method of feeding the carbons. To us, Mr. Turbayne's assertion that "the best foundation design for an arc lamp for direct-current working would undoubtedly be that of the *non*-differential variety," is simply unintelligible. The essential property of lamps run in series is that they shall regulate without influencing one another, and without any change of current. How can any such independence be obtained where there is a series feed?

Under the pretext of overhauling their International telegraph system, the French authorities are apparently projecting some scheme of submarine cable laying, which will require to be carefully watched. The Ministers of War, of Marine, and of Foreign affairs are represented on a commission, which includes some "superior functionaries" of the Colonial Department. The matters discussed are described as "particularly urgent," and a Sub-Commission has been already charged with elaborating a comprehensive plan of submarine telegraph cables. It has not transpired what peaceful purpose these cables are to serve, and it would be hard to discover any colonial or commercial interests pertaining to France that are not amply guarded by existing cables. All the same, we can take no exception to her laying a few more; and as she has been spending large sums of money on subsidies to enable French makers to manufacture their own cables at home, and to support existing French lines, we are content to let them continue trying their hands at it, and shall grudge them no success. But this is a matter which does not concern British cable interests alone. The British Government ought to have their eyes open as to these "urgent" French enterprises.

The Hutin-Leblanc Patents.—The Maison Farcot has purchased the Hutin-Leblanc patents, and are about to build a 750 kilowatt alternate-continuous-current transformer.

The Late Mr. Henry Weaver.—Probate of the will, dated March 24, 1887, of the late Mr. Henry Edward Weaver, who died recently at Folkestone, aged 68 years, leaving personalty valued at £83,965, has been granted to the executors.

Appointment.—The Indian Government have selected Mr. G. Church for the appointment of Mechanical Engineer to the Indian Telegraph Department. The intention to appoint an Electrician to the same Department has been abandoned.

Finsbury Technical College.—Prof. A. B. W. Kennedy has arranged to give a special course of two lectures on "Engine and Boiler Testing." The first was delivered last night, and the second will be delivered on the 21st, at 8 o'clock.

Compensation for Hysteresis.—We have received, too late for publication this week, some further contribution from Mr. Vignoles on the subject of compensation for hysteresis (see *The Electrician*, November 3rd, p. 11), which we hope to publish next week.

Telephonic Communication between Denmark and Sweden. The telephonic service between Denmark and Sweden was formally opened at two o'clock on Tuesday last by King Christian and King Oscar, who exchanged congratulatory messages upon the new means of intercourse established between the two countries.

Cheap Telephones.—A telephone for 36kr., or £2 per year, can, says *Industries and Iron*, now be had all over Stockholm, the Stockholm General Telephone Company having decided to meet the great demand for cheap telephones. Hitherto only one district of the town has been supplied at this low rate by the Telephone Company.

Local Authorities and Electric Lighting.—Mr. H. Scholey, of 22, Paternoster-row, has, we are informed, undertaken the organisation of a system of lectures to be delivered in towns where the local authorities are contemplating the adoption of electric lighting. The primary object of these lectures will be to furnish general information of the most recent character.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	October 25th.
Cayenne-Vizeu	November 25th.
Jamaica-Colon	November 25th.
Bissao-Bolama	November 24th.
Kotonou-Accra	December 4th.
Lagos-Brass	December 4th.

The Feeder Patent in the United States.—The General Electric Company, says our New York correspondent, have instituted an action against the Westinghouse and Western Electric Companies for infringement of their feeder and main patent. It s understood that the suit was deferred by an arrangement with the Chicago Exhibition authorities until the close of the Exhibition.

Carbons for Arc Lamps.—A recent number of the *Electro Techniker* describes an improvement in arc-light carbons, as used by the firm of Krupp, in Essen, which consists in saturating the carbon, or mixing the carbon paste from which they are made, with tungstic acid, or tungstates; this is said to increase the number of hours during which the carbon will last in the ratio of 18 to 21.

Personal.—Mr. H. J. S. Heather will sail shortly for South Africa, in charge of the electrical plant supplied by Messrs. Goolden and Co. to Moodie's Gold Mines and Exploration Company. The plant will comprise two 1,500 volt continuous-current generators, driven by Pelton wheels. The current will be transformed down after transmission, and distributed to the motors driving the stamps.

Tests of Gas Burners.—The footnote on p. 113 of our last issue on the omission of the cost of mantles and glasses of Welsbach burners, implied no inadvertence on the part of the observers, for it was obvious that their research did not deal with prolonged tests. The statement that the efficiency

Digitized by Google

was only 10 c.p. per cubic foot per hour could not, however, be allowed to pass without comment.

The Legal Aspect of Motor "Bucking."—Liability for, damage caused by a "bucking motor" has become a matter of lgal importance in the United States. The Supreme Court of Minnesota holds that "failure to properly test a motor, which was known to have bucked, before sending it out in service, together with use of a low dash on driver's platform combine to make the company liable for damages for death of motorman who was killed by being thrown over the dash when the motor bucked." It is practically the same interpretation of the law which has long prevailed as regards the use of animals in car service known to be ferocious and dangerous.

The Unit of Illumination.—At the meeting of the American Institute of Electrical Engineers on November 15th, Prof. Houston announced the following Committee to take up certain lines of work left unfinished by the Electrical Congress of Chicago, more especially the determination of a practical Unit of Illumination:—Prof. E. L. Nichols (Cornell University), Prof. Ch. R. Cross (Mass. Institute of Technology), Mr. Thomas A. Edison, Dr. Louis Duncan (Johns Hopkins University), Prof. F. B. Crocker (Columbia College), Prof. R. A. Fessenden (Western University of Pennsylvania).

Royal Institution.—The following are some of the lecture arrangements before Easter: Prof. Dewar, six lectures (adapted to a juvenile auditory) "On Air: Gaseous and Liquid"; The Right Hon. Lord Rayleigh, six lectures on "Light," with special reference to the optical discoveries of Newton. The Friday evening meetings will begin on January 19th, when a discourse will be given by Prof. Dewar on "Scientific Uses of Liquid Nitrogen and Air"; succeeding discourses will probably be given, amongst others, by Prof. Silvanus P. Thompson and The Right Hon. Lord Rayleigh.

Proposed Association of Technical Institutions.—At a meeting of the Principals and Directors of technical schools and colleges, held at the Manchester Technical School, last month, it was unanimously agreed "that it is desirable that an association of technical institutions be formed." A second meeting has been convened, and is to be held on January 26th next at 2.30 p.m., at the meeting room of the Society of Arts, Adelphi, W.C., at which it is expected that this association will be formally constituted. Efforts are being made to render this meeting as widely representative as possible.

The Trolley in Chicago.—Last week's mail brought us American papers jubilant with the triumph of the trolley in Chicago, which was, we were told, about to be adopted by every one of the Chicago tramway companies, even by those which had at first raised deadly opposition to the trolley. This week the note is changed, and we listen to the wail of the electrical Press over the "defeat of the trolley in Chicago." It seems that the newspapers have been leading a fight against the overhead wire, with the result that public sentiment against this street excrescence was strongly excited, and the efforts to introduce it failed.

Lighthouse Communication.—In reply to a question in the House of Commons last week, the Postmaster-General said that the number of lighthouses on the coasts of the United Kingdom which had been provided with electrical communication was 22. This number included Lundy Island, Fair Isle, and the Gunfleet Pile Lighthouse. The Royal Commission on Electrical Communication with Lighthouses had recommended that communication be also extended to Caldy Island, the Tuskar, and the Fastnet. With regard to floating lightships, the President of the Board of Trade said that the work of connecting with the shore by electric cable the North Goodwin and the Kentish Knock light vessels was being proceeded with as rapidly as practicable.

Electric-Light Carbon Making.—At a recent meeting of the Academy of Medicine, M. Lancereaux exhibited the lungs of a polisher of electric-light carbon terminals, the said organ being transformed into veritable blocks of carbon. The deceased was, up to the age of thirty-six years, a vigorous stonemason. He was then transferred to a workshop eight metres long by seven broad, where, with eight other men, he was engaged in polishing on stone mills carbons for electric-lighting purposes. The shop was so badly ventilated that sometimes the men could not distinguish each other through the charcoal and stone dust filling the atmosphere. Better ventilation and the use of a respirator would have probably rendered M. Lancereaux's pathological exhibit less interesting.

Inverted Arc Lighting.—Messrs. C. A. Parsons and Co., of Newcastle, have just completed a rather interesting electric-light installation for the L. and T. Waterproof Garment Company, Cornbrook, Manchester. For the most part arc lamps are used for lighting the workrooms. These lamps are suspended from the ceiling and are inverted. The light cannot be seen, as it is within a large reflector which shows the rays of the light upon the white-washed ceiling, which acts as a very large reflector and distributes the light in a soft daylight manner. Messrs. Parsons are at present engaged in supplying and erecting over 60 inverted arc lamps for workshop lighting in various parts of the district. The work at Cornbrook was carried out by Mr. J. Moore, of Bolton, Messrs. Parsons and Co.'s local agent.

French Cable Projects.—A Commission has been instituted by the French Posts and Telegraphs Department to study the question of the International telegraphic communications of France. This Commission, which comprises several Senators and Deputies, Delegates from the Ministries of Foreign Affairs, War, and Marine, and Commerce and Industry, as well as superior functionaries of the Colonial Department and of the Posts and Telegraphs Administration, met on Friday last for the first time. The work of the Commission consists in drawing up the programme of all the telegraphic communications the establishment of which is deemed necessary in the interest of France, the estimation of the cost of the various lines, and the order in which the works should be carried out. After an exchange of views, in the course of which it was declared that it is now more imperiously necessary than ever to organise a system of French submarine telegraph cables, the Commission charged a Sub-Commission to elaborate a comprehensive plan, and to prepare certain projects, the carrying out of which was regarded as particularly urgent.

Coventry.—At the meeting of the Town Council on Tuesday last, the Electric Lighting Committee presented their report, in which it was stated that Mr. A. H. Preece had been called upon to advise the Committee on the selection of a tender for the electric lighting of the town. Mr. Preece had recommended the acceptance of Messrs. Hammond and Fowler's tender, subject to certain small modifications, which had been agreed to. The Committee had received an offer from Mr. Hammond (who is associated with Messrs. Fowler and Co. in this matter) to retire from the contract in order to act as consulting engineer to the Corporation for the execution of the works at a commission of 5 per cent., the contract being placed with Messrs. Fowler and Co. at 5 per cent. less than the figure named in the tender. The Committee recommended that this suggestion be adopted, and that the tender of Messrs. Fowler and Co. be accepted on condition that that firm guaranteed the efficiency of the generating plant to be not less than 75 per cent. at full load, and subject further to the sanction of the Local Government Board for the necessary loan. The tender, including the trenching of the streets, amounts to nearly £10,000. The Committee further recommended that the amount for which borrowing powers be asked from the Local Government Board should be altered to £20,000, instead of the original sum of £15,000. The report was adopted.

The Northern Society of Electrical Engineers.—Within the last few weeks a new Society, with the above name, has been founded, with its head-quarters in Manchester, "to hold meetings for the promotion of electrical science, and its commercial and other applications, and for social intercourse between members." It has for some time past been felt that little or no opportunity has been afforded the members of the electrical profession and trades—now very numerous—in the Midland and northern counties of meeting outside London, for the purpose of scientific discussion and social intercourse. A move-

Digitized by Google

ment was recently set on foot by two or three gentlemen in order to bring some local members of the profession together to discuss the matter. The result has been that several meetings have been held, and the new Society founded. It is pointed out that the Society is not founded with any view of rivalry or opposition to the existing Institution of Electrical Engineers, but simply to enable members of the profession, who are unable to attend meetings in London, to do so in the provinces, and at the same time to become better acquainted with each other. A considerable number of gentlemen have already joined the Society, and invitations have been posted to members of the profession within range of Manchester inviting their co-operation. At present it has been decided to hold the meetings in Manchester, but it is expected that at an early date meetings will be arranged for at other important provincial towns. The hon. secretary is Mr. John Darney, 102, Portland-street, Manchester.

Battery Cars in New York.—Official figures have been published of the performance of the Waddell-Entz storage batteries on the Second-avenue line in New York. This road was started on June 1, last, and has been in operation since, between Ninety-fourth and One Hundred and Twenty-ninth streets. Ten cars were run, but lately the number has been increased to eighteen. The battery depreciation has been 1.54 cents a car mile. The total cost of operation is given as 9.32 cents, which it is claimed can be reduced to 5.29 cents, with the eighteen cars now running. The Waddell-Entz batteries are known as the zinc-copper alkaline type. A short description of this cell was given in *The Electrician*, Vol. XXVII., p. 84. The positive plates are of woven copper wire, insulated with cotton. The negative plates are the steel partitions of the iron case, which case serves the double purpose of being one electrode and holding the solution. The copper positive plates are slipped in between the steel partitions in the case, the cotton insulation preventing a short circuit. The solution is zinc dissolved in potash. In charging, the copper is oxidised and zinc deposited on the iron sides and partitions of the cell, this action being reversed, of course, in the discharge. In practice it has been found that the main weak point in the cell and the one which causes the chief expense of battery maintenance, is the cotton insulation on the positive mat. The electromotive force of these cells is less than half that of a lead cell, being from 0·82 to 0·89 volt, as against 1·8 to 2·2 volts. The amperage, is, however, sufficiently large to make up the difference.

The City Lighting.—At the meeting of the Commissioners of Sewers on Tuesday last, Mr. Burmester moved "That the gas standards be removed from the streets now lighted by electricity, and that it be referred to the Streets Committee to carry this out." He said this was the legitimate outcome of the report of the engineer on electric lighting. The total number of hours during which the lamps were burning was 783,343, while the total number of lamp hours failure was only 374. The percentage of failure in lamp hours was thus 0·047, or what was equivalent to one hour's failure in every 1,230 hours. He thought that justice ought to be done to the Company by giving them credit for the way in which they had lighted the streets. The total amount of gas consumed on account of the failure of the electric light during the six months had cost the Commission 1s. 2d., whereas the engineer reported that the Commission were paying for maintenance of the gas lamps at the rate of £1,182 per annum. Mr. Turner said the six months just past was the best part of the year. They were coming to the worst period, and it was absolutely inadvisable to remove the lamps. If the light failed the City would be in a dreadful state. The standards should be allowed to remain to the end of March, and he moved as an amendment that they should not be removed till March 31st. The amendment was negatived and the motion agreed to. The Chairman said that he had sent a letter he had received from one of his constituents on the subject of the delay in connecting up intending consumers to the Electric Light Company, and he had received a reply, which ought to be made public. In this letter the secretary of the Company said that the Company was doing all it possibly could to get the work through, but that with regard to the distribution plant the contractors had not kept faith, and transformer equipment ordered over a year ago was not yet delivered; the contractors alleged all sorts of excuses for this—strikes, non-delivery of proper raw material, and so on. The Company had now, however, made such arrangements as would overcome the transformer difficulty. It was only comparatively recently that they obtained sites for the 22 transformer stations. As far as the secretary could see, all (except the outlying areas like the St. James's-square, Redcross-street, and Fetter-lane ones) would be completed at different dates within, say, two months. Some little delay also arose in joining the cables as good jointers were scarce; and it would not be safe to employ other than fully-skilled workmen. It must not be forgotten that the Company was already supplying over 60,000 lamps, and had completed services ready to join up nearly 15,000 more.

Electrical Canal Boat Propulsion on the Erie Canal.—The first practical test of electricity for the propulsion of boats on the canals is, says the *Electrical Engineer* of New York, now history. By an act of the last Legislature, the sum of $10,000, or as much of that sum as should be necessary, was appropriated to carry into effect Governor Flower's recommendations regarding the investigation of electricity as a motive power on the canals. Parties interested were invited to make experiments, under the supervision of the superintendent of public works. A number signified their intention to participate, but only one plan, that jointly of the Westinghouse Company of Pittsburgh and the Niagara Power Company of Niagara Falls, materialised, and the Westinghouse method was tested on Saturday, Nov. 18th. On Monday, November 13th, a party of *employés* of the Rochester Electric Railway Company began stringing a trolley wire in position, for a distance of about one mile, east of the village of Brighton. All was ready for work in five days, and the current from the power house of the Rochester Electric Railway was turned on. In the meantime, a full-sized steam canal boat had been fitted and put in order for the test of the weighlock at Rochester, and was towed to Brighton, ready for the experiment. It moved off readily on the first trial, and made the private run without incident. The overhead construction consists of two parallel lines of No. 0 copper trolley wire, strung 5ft. apart, about one-third of the distance across the canal from the bank or heel path. The positive wire was connected with the feeder wire on the Rochester Electric Railway, and the negative with the rail of the Park avenue street railway track, on which there is no supplementary ground wire. In fact, the overhead construction was essentially the same as that for a double track street railway, where double trolley lines are used. In this experiment dependence was placed on the railway track for the return, and but one trolley was used. For the official test the next day ordinary street railway trolleys were used, but of course this form is not an ultimate type, and it will be superseded in practical work by an especially designed overrunning trolley, so constructed as to permit the boat to move in any part of the canal, while the trolley will follow the wire constantly. The boat used was an ordinary steam canal boat, with a propeller of the antiquated dish-pan type, not one-third of the surface of which, apparently, is active in propelling the boat. In preparing for the test, the engineers removed the boiler and engine and replaced them with two 25-H.P. Westinghouse street railway motors, of standard type. The motors were connected directly to the propeller shaft. The connection was made by simply taking out the bolts of the coupling which held the engine shaft, and making the coupling to the motor shaft instead of to the engine shaft. For the official test the Rochester Electric Railway undertook to supply 500 volts, and the apparatus was designed to do its work under these conditions. The actual voltage during the official test was from 300 to 250, with a current of 60 amperes, making about 20 E.H.P. During the official test the shaft made about 60 revolutions per minute, and the speed of the boat approximated four miles an hour against the current and the wind. The extremely difficult curves, the lock and the bridges, furnished typical conditions in canal work, and were taken without difficulty, and the test, in all respects, was very satisfactory to the canal officials and the electricians.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 112.)

Effort and Resistance.—In every engine there are two sets of forces which determine the motion and the work done. These are: the effort, or driving forces; and the resistance, or opposing forces. In the foregoing considerations about the interchange of energy between bodies it has been assumed that the acting force is exerted directly along the line of motion, and that the resisting force has been exerted directly backwards along the line of motion. In engines the driving and resisting forces are often inclined to the direction of motion. In such cases we take the sum of the components of the acting forces measured along the line of motion, and call this total component the *effort*; and we take the sum of the components of all the resisting forces at the same place, measured along the same line, and call this total component the *resistance*. The total effort requires that every acting force shall be taken into calculation; and the total resistance requires that every opposing reaction or force shall be considered also. When we have followed this process strictly we shall always find that the total effort at any point in the engine is exactly and always equal to the total resistance at this same point. This is the application of Newton's third law to engines. What we have previously said about the relation between acting or opposing forces and energy, work and power is now to be taken as strictly applying to engines where the effort and the resistance assume the place of the acting and opposing forces. The energy exerted is equal to the product of the effort into the distance through which it acts, and the energy absorbed is equal to the product of the resistance into the distance through which it is overcome, while the power is determined by the product of either effort or resistance into the velocity of the moving point on which they are acting. In every engine, however, there are numerous opposing forces which contribute to the total resistance, and these may all be classed under two heads—useful resistances and wasteful resistances. In other words, a fraction of the total resistance is useful and the remainder is prejudicial.

Useful and Prejudicial Resistances.—The useful part of the resistance arises from the reaction of the mechanism upon which useful work is being done, as from the magnetic torque of the dynamo armature which opposes the motion which produces the current. Or, the useful part of the resistance may wholly or partly arise from another cause, namely, from the inertia reaction of the flywheel in which energy is being usefully *stored* for future use. The useful resistance may therefore be divided into: (1) The reaction of the directly useful work, and (2) the inertia reaction of the storage of energy. Prejudicial resistances arise from the unavoidable or improperly removed forces between the relatively moving parts of the engine or gearing, as from the friction of sliding or rolling parts, or the imperfect elasticity of parts which are in vibration or in collision with one another.

It is impossible to completely remove either of these two sources of prejudicial resistance; for no two surfaces are there, but their relative sliding or rolling will develop friction; and there are no materials which will withstand vibration and shock, or collision, without internal forces which will cause a prejudicial resistance. The resistance of friction between two solid surfaces in sliding motion is equal to the product of their total normal pressure against one another into the coefficient of friction of their surfaces. This coefficient is not independent of the intensity of pressure between the surfaces, especially if there is a layer of oil interposed between the surfaces, and is found to increase with an increase of pressure in most cases. Neither is it strictly independent of the velocity of relative motion, being greatest when the surfaces are relatively at rest—when it is called *statical* friction—and diminishing at very high speeds; but for the usual range of relative velocities in machinery it may be assumed that the coefficient of friction is, with solid surfaces, practically independent of velocity. Rolling friction is chiefly due to the slip of the surfaces which are rolling on one another, and is directly proportional to the percentage of slipping which occurs. The friction between surfaces which are not solid, as in water or wind engines, will be considered in the sections devoted to these engines, as it follows quite different laws.

Inertia and Moment of Inertia.—Inertia resistance arises in machinery when any portion of the moving parts is accelerated; and since the acceleration of a body may either tend to increase or to decrease the velocity of the body, this resistance may be either positive or negative. When it is negative it is virtually a portion of the total effort, and may be treated as such. The force which is required, in order to accelerate any body which is not acted on by any external opposing force, is equal to the product of the mass of the body into the linear acceleration which is to be produced. This force is numerically equal to the resistance of the body to change of motion, and it is usual to call this resistance the *inertia reaction*. There are two principal cases of inertia reaction which arise in machinery: the one occurs in simple harmonic motion, and the other occurs in any change of speed of circular motion. We will deal with these separately.

Simple harmonic motion (S.H.M.) is very commonly called reciprocating motion, and practically occurs in the piston of a steam engine. Let a point, P (Fig. 1), travel round a circle

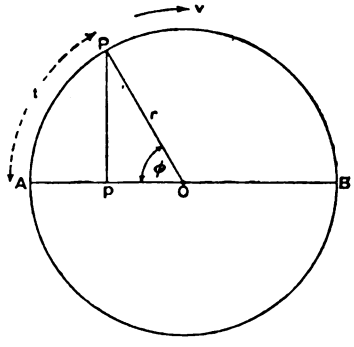

Fig. 1.

of radius, r, with a uniform velocity, v, or speed, N, revolutions per minute; and let another point, p, travel to and fro on the horizontal diameter A B in such a manner that it is always in a vertical line with the point P. Then the reciprocating motion which p will describe in A B is called a simple harmonic motion. Let V be the velocity of the reciprocating point at any time when the radius to the point, P, makes the angle, ϕ, with the horizontal radius, O A. Then

$$V = v . \sin \phi, \quad \ldots \ldots \quad (6)$$

and

$$\phi = \frac{2 \pi t}{T}, \quad \ldots \ldots \quad (7)$$

where t is the time taken to move through the angle ϕ, and T is the periodic time or time of one complete revolution of P.

Whence,

$$V = v . \sin \frac{2 \pi t}{T}, \quad \ldots \ldots \quad (8)$$

and the acceleration of p, which has this velocity, is

$$a = \frac{dV}{dt} = \frac{2 \pi}{T} . v . \cos \frac{2 \pi t}{T} . \quad \ldots \ldots \quad (9)$$

The acceleration multiplied by the mass accelerated gives the force exerted in causing the acceleration, and is equal to the inertia resistance of the mass f_i;

$$f_i = M a = \frac{W a}{g} = \frac{2 \pi W v . \cos \frac{2 \pi t}{T}}{g T} . \quad (10)$$

This gives the inertia resistance in pounds when all the other quantities are also in gravitation engineering units. The maximum value of this force is

$$f_i \,(\max) = \frac{2 \pi W v}{g T}, \quad \ldots \ldots \quad (11)$$

and occurs when the angle ϕ is zero or 180deg., *i.e.*, at the beginning and end of the to-and-fro motion. In the first case

Table I.—*Moments of Inertia* (I) *of Homogeneous Rigid Bodies.*

Name of figure.	Dimensions in feet.	Axis of rotation.	Values of I. In terms of W = weight in pounds.	Values of I. In terms of Δ = density in pounds per cubic foot.
Solid circular cylinder ...	Length = L. Diameter = D.	Through centre of D, parallel to L.	$\frac{W}{g}\left(\frac{D^2}{8}\right)$	$\frac{\Delta}{g}\left(\frac{\pi D^4 L}{32}\right)$
Ditto..............................	Ditto.	Through centre of L, parallel to D.	$\frac{W}{g}\left(\frac{D^2}{16}+\frac{L^2}{12}\right)$	$\frac{\pi\Delta}{g}\left(\frac{D^4 L}{64}+\frac{D^2 L^3}{48}\right)$
Ditto..............................	Ditto.	Through end of L, parallel to D.	$\frac{W}{g}\left(\frac{D^2}{16}+\frac{L^2}{3}\right)$	$\frac{\pi\Delta}{g}\left(\frac{D^4 L}{64}+\frac{D^2 L^3}{12}\right)$
Hollow circular cylinder..	Length = L. Outer diameter = D. Inner diameter = d.	Through centre of D, parallel to L.	$\frac{W}{g}\left(\frac{D^2+d^2}{8}\right)$	$\frac{\Delta}{g}\left(\frac{\pi L (D^4-d^4)}{32}\right)$
Ditto..............................	Ditto.	Through centre of L, parallel to D.	$\frac{W}{g}\left(\frac{D^2+d^2}{16}+\frac{L^2}{12}\right)$	$\frac{\pi\Delta}{g}\left(\frac{(D^4-d^4)L}{64}+\frac{(D^2-d^2)L^3}{48}\right)$
Ditto..............................	Ditto.	Through end of L, parallel to D.	$\frac{W}{g}\left(\frac{D^2+d^2}{16}+\frac{L^2}{3}\right)$	$\frac{\pi\Delta}{g}\left(\frac{(D^4-d^4)L}{64}+\frac{(D^2-d^2)L^3}{12}\right)$

it is a positive maximum, in the second case it is a negative maximum. In intermediate positions, let the distance of the reciprocating point p from the centre, O, of its amplitude, stroke or travel, A B, be D feet; and let the total stroke, A B, be L feet. Then

$$D=\frac{L}{2}\cdot\cos\frac{2\pi t}{T}. \quad . \quad . \quad . \quad . \quad . \quad (12)$$

The ratio of a to D at any point is

$$\frac{a}{D}=\frac{4\pi v}{LT}=\text{a constant.} \quad . \quad . \quad . \quad (13)$$

It is a simple property of S.H.M. that the acceleration is directly proportional to the displacement from the middle part of the stroke. From (13) we get

$$a=\frac{4\pi v D}{LT}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

and, by (10),

$$f_i=\frac{4\pi v D W}{LTg}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

This force may conveniently be expressed in terms of N, the revolutions per minute of the point P by eliminating v and T,

$$f_i\,(\text{max})=\frac{2WL}{g}\cdot\left(\frac{\pi N}{60}\right)^2. \quad . \quad . \quad . \quad (16)$$

It is notable that, other things being equal, this inertia resistance varies as the square of the speed of reciprocation or revolution.

Turning next to the inertia of a rotating body, let us consider a particle of mass, m, at the end of a rigid radius, r. If this is at rest it will require a force to give it N revolutions a minute, or a velocity of v feet per second in any given time, t. This force, f, will be equal to

$$f=\frac{m v}{t}=\frac{2\pi r N m}{60\,t}. \quad . \quad . \quad . \quad . \quad . \quad (17)$$

Multiply both sides of this equation by r, and we have

$$\tau=f r=\frac{2\pi N}{60\,t}\cdot(m r^2). \quad . \quad . \quad . \quad . \quad (18)$$

This gives the torque required to produce any given acceleration in the revolving mass, the acceleration being angular. The expression within the brackets is called the *moment of inertia* of the mass about the centre of rotation, and stands in respect to torque and angular acceleration in the same relation that mass stands to force and linear acceleration. Or,

$$\text{Linear acceleration}=\frac{\text{Force}}{\text{Mass}},$$

$$\text{Angular acceleration}=\frac{\text{Torque}}{\text{Moment of inertia}}.$$

Where, as is always the case, the mass is not concentrated at the same radius, we have to take the resultant inertia resistance of all the mass particles, or

$$\Sigma\, m r^2=\text{Moment of Inertia}=\text{I}.$$

Since the angular velocity, ω, acquired in any time, t, after starting from rest, is equal to the product of the acceleration by the time the number of revolutions per minute produced by an average torque τ upon a moment of inertia, I, which is free to move, will be

$$N=\frac{60\,\tau\,t}{2\pi I}. \quad . \quad . \quad . \quad . \quad . \quad (19)$$

Or this speed will be added to or subtracted from any initial speed, according as the torque is assisting or opposing motion. Assuming the rotating body to start from rest, it will perform a certain number of complete revolutions, R, in getting up the speed N, equal to

$$R=\tfrac{1}{2}N\,t. \quad . \quad . \quad . \quad . \quad . \quad (20)$$

Stored Energy.—Therefore the work done by the force, f, which, acting at the radius, r, turns the resisting mass, is equal to

$$W=f\times 2\pi r\times(\tfrac{1}{2}N\,t)=\pi N\tau t. \quad . \quad . \quad (21)$$

And, from (19) we get the value of τ, which inserted in (21) gives

$$W=\tfrac{1}{2}I\left(\frac{2\pi N}{60}\right)^2=\tfrac{1}{2}I\,\omega^2. \quad . \quad . \quad . \quad . \quad (22)$$

Here the work is represented as a condition depending only upon the motion of the body, or is, as we say, kinetic energy stored in the rotating mass. Hence

$$\text{Energy of rotation stored in mass}=\tfrac{1}{2}I\left(\frac{2\pi N}{60}\right)^2.$$

The power being expended at any instant in storing this energy can be obtained from the torque and angular velocity at that instant. For since power P is the product of force into velocity, we have

$$P=f\times v=\tau\left(\frac{v}{r}\right)=\tau\left(\frac{\pi N'}{30}\right), \quad . \quad . \quad (23)$$

where N′ is any speed during the acceleration. Expressed in horse-power this is

$$\text{H.P. (stored)}=\frac{2\pi N'\tau}{33{,}000}, \quad . \quad . \quad . \quad (24)$$

where τ if the torsional resistance of inertia; so that, expressing τ in terms of I, we get

$$\text{H.P. (stored)}=\left(\frac{2\pi}{60}\right)^2\frac{I N'}{550}\cdot\frac{dN'}{dt}. \quad . \quad . \quad (25)$$

The foregoing considerations of the opposing force, absorption of power, and storage of energy due to a rotating mass, is applicable to flywheels, in whole or in part, by means of Table I., which gives the moments of inertia for the most common shapes of portions of, or of complete, flywheels.

(To be continued.)

COMMUTATION IN MOTORS AND DYNAMOS.

BY J. A. KINGDON.

A motor is usually regarded as merely a reversible dynamo, having the current in the armature reversed, and the brushes displaced from the neutral position in a backward direction, instead of, as in the case of a dynamo, in a forward direction, so as to obtain sparkless commutation. There is, however, a real difference, which appears to have been overlooked, between a motor and a dynamo. This difference is in the process of commutation of the current in the armature conductors, and in the effect of the reversal of current in the coils under the brushes, upon the magnetic field. In order to understand this difference it will be supposed that the brushes are in the neutral position, without lead or trail, midway between the poles, and that the commutator bars are comparatively few in number, so as to make the effects of the reversals more marked. It will also be supposed that the reversal of the current takes place instantaneously in the coils under the brushes, and that between two consecutive reversals there is a short period during which the current in the armature conductors is unaltered in direction or strength, although the armature is rotating during that period. Small circles containing dots represent in section conductors carrying positive currents, and the circles containing crosses represent conductors with negative currents. The relations between these and magnetic flux are shown in Fig. 1, which represents a bar magnet, and the relative positions of the positive and negative currents of its exciting coil and the direction of the magnetic flux.*

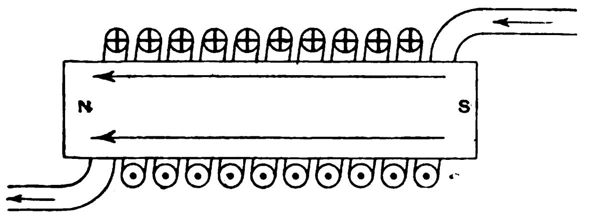

Fig. 1.

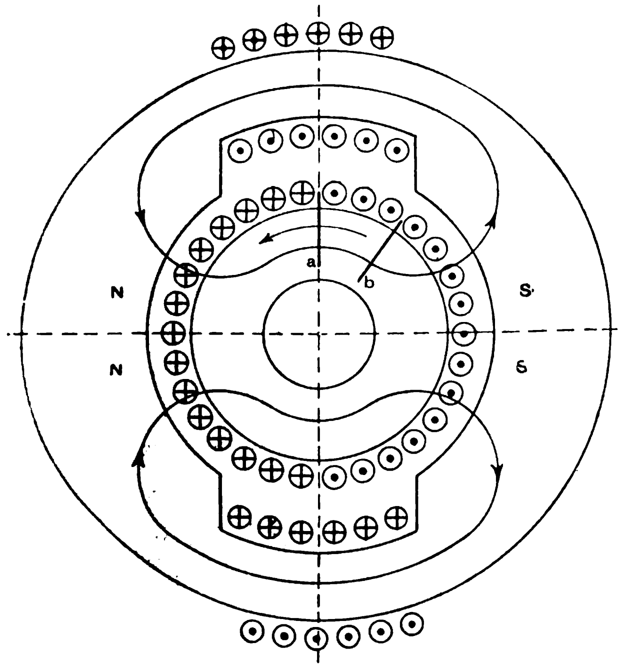

Fig. 2.—Motor.

Fig. 2 is a diagram of the magnetic circuits and the current directions of a motor whose armature is rotating in the direction of the arrow. The lines *a* and *b* represent connectors from commutator bars to the armature conductors. The current is supposed to be flowing from a commutator bar up the connector *a*, and then to divide and pass in both directions round the armature, in the positive direction in the conductors behind *a*, and in the negative direction in the conductors in front of *a*. The exciting coils are indicated by sectional conductors, and the magnetic circuits by lines threading the coils and traversing the iron armature core. The magnetomotive forces acting on these circuits is, as is well known, the aggregate of the magnetomotive forces of the field coils and of the armature coils. In the majority of dynamos and motors, the magnetomotive force due to the armature currents reduces the aggregate magnetomotive force acting on the circuit. Figs. 3 and 4 are similar diagrams for different positions of the armature of the motor. Figs. 5, 6, and 7 are corresponding diagrams for a dynamo. The lower parts of the figures, which are cut away, are similar to the lower part of Fig. 2.

* The dots in circles may be considered to represent the points of arrows shooting upwards; and the crosses, the tails of arrows shooting downwards.

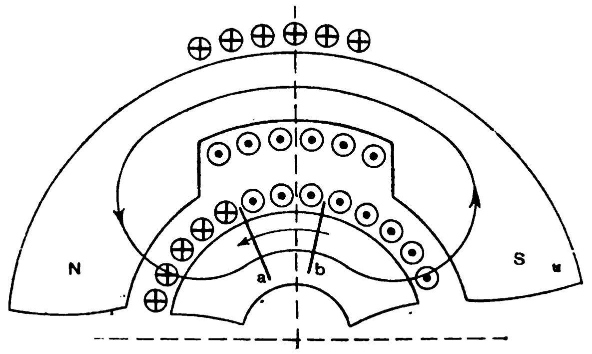

Fig. 3.—Motor.

In Fig. 2 it will be seen that the number of positive armature conductors within the magnetic loop is the same as the number of negative armature conductors, so that their aggregate magnetomotive force acting round the circuit is *nil*. The magnetomotive forces acting on the circuits in Fig. 2 are those due to the exciting coils alone. In Fig. 3 there are seven positive armature conductors within the loop, but only three negative armature conductors. Hence the magnetomotive force acting round the circuit in Fig. 3 has been increased by that due to the excess of the positive over the negative conductors. In Fig. 6 there are seven negative conductors and three positive conductors. Hence there is a reduction of magnetomotive force acting round the circuit in Fig. 6.

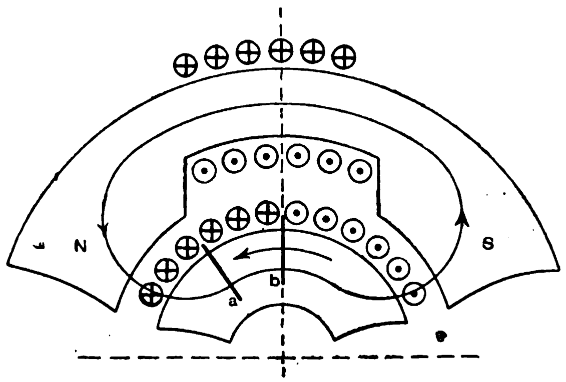

Fig. 4.—Motor.

In Fig. 3 the armature of the motor is supposed to have rotated through an angle, so as to bring the connector *b* nearly vertical, but no reversal has taken place of the current in the conductors between *a* and *b*, and the current in these conductors is still positive, as in Fig. 2. It will be seen that the aggregate magnetomotive force acting round the circuit is that due to four armature conductors, in addition to the magnetomotive force of the six conductors of the exciting coil. The rotation of the armature of the motor has consequently increased the magnetomotive force acting round the circuit, and there is a corresponding increase in the magnetic flux.

Digitized by Google

In Fig. 4 the armature of the motor has rotated so as to bring the connector *b* vertical, and the reversal of the current in the conductors between *a* and *b* is supposed to have taken place. In fact, the current has been commutated, and flows up the connector *b* instead of up the connector *a*, as in Figs. 2 and 3. The result of the commutation is that the conductors between *a* and *b* have negative instead of positive currents, and the aggregate magnetomotive force acting round the circuit has now the same value that it originally had in Fig. 2. The effect of the commutation has therefore been to reduce the aggregate magnetomotive force. It is thus clear that in the case of a motor, supposing that there is first a period of rotation of the armature without commutation, and then an

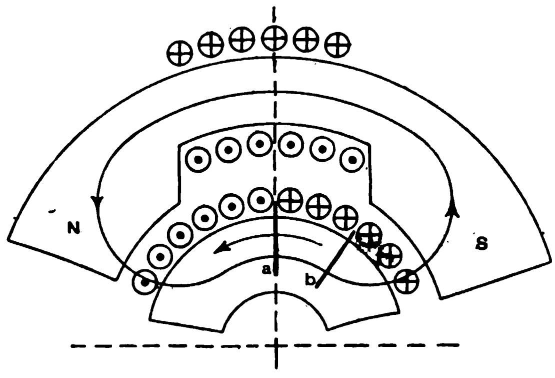

FIG. 5.—Dynamo.

instantaneous reversal or commutation of the current in the conductors under the brush, the effect of the rotation of the armature is to tend to strengthen the magnetic flux, and the effect of commutation is to tend to reduce the magnetic flux.

If the process of commutation in the case of a dynamo is analysed in a similar manner a difference will at once be evident. In Figs. 5, 6, and 7, which are diagrams for a dynamo, the direction of rotation of the armature, and the directions of the exciting current and magnetic flux, are the same as in Figs. 2, 3, and 4, but the direction of the armature current is reversed.

In Fig. 5 the current generated by the dynamo flows from the armature conductors down the connector *a* to the commutator and brush. The aggregate magnetomotive force is that due to the field coils alone, as the number of positive

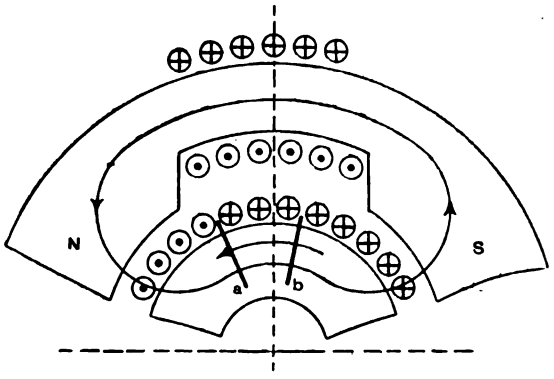

FIG. 6.—Dynamo.

armature conductors within the magnetic loop is equal to the number of negative conductors. In Fig. 6 the armature of the dynamo is supposed to have rotated so as to bring the connector *b* nearly vertical, but no commutation has taken place, and the current in the conductors between *a* and *b* is still negative. The result is that there are more negative conductors within the loop in Fig. 6 than there were in Fig. 5. The additional negative armature conductors in Fig. 6. tend to counteract the positive conductors of the field coils. Hence, in the case of a dynamo, the rotation of the armature tends to reduce the magnetic flux.

In Fig. 7 commutation is supposed to have taken place, and the current flows down the connector *b*. It will be evident that the aggregate magnetomotive force has been increased, and has now the same value that it originally had in Fig. 5.

Thus, in a dynamo, the effect of the armature rotation is to reduce the magnetomotive force acting round the circuit, and to tend to weaken the magnetic field, and the effect of commutation is to increase the magnetomotive force and to tend to strengthen the field.

It is, perhaps, unnecessary to point out that in a well-designed dynamo, with its brushes properly adjusted, the two processes go on simultaneously, so that there is practically no variation of the magnetic flux, and the commutation consequently takes place without sparking.

The conclusions arrived at may be summed up as follows :—

(1) In a *motor* the armature rotation tends to increase the aggregate magnetomotive force of the field and armature coils, and to strengthen the magnetic field.

(2) In a *dynamo* the armature rotation tends to reduce the aggregate magnetomotive force and to weaken the field.

(3) In a *motor* the effect of commutation is to tend to reduce the aggregate magnetomotive force and to weaken the field.

(4) In a *dynamo* the effect of commutation is to tend to increase the aggregate magnetomotive force and strengthen the field.

Now it is well known that iron is very sensitive to slight increases of a magnetomotive force acting on it; and, on the other hand, that it is comparatively insensible to considerable reductions of magnetomotive force. Some tests made by Prof. Ewing* on a length of annealed iron wire showed that

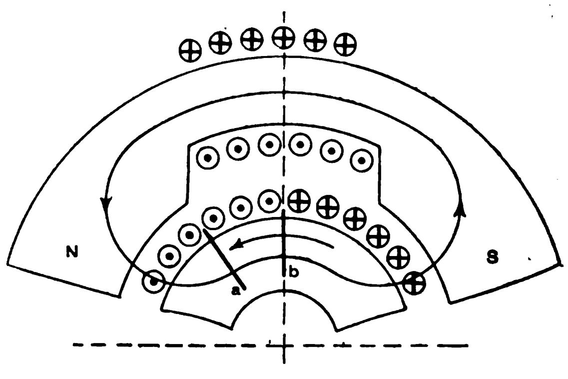

FIG. 7.—Dynamo.

when the induction in the iron was 6,800, a decrease of 30 per cent. in the magnetomotive force caused a decrease in the induction of less than 2 per cent., while an increase of 30 per cent. in the magnetomotive force produced an increase in the induction of over 60 per cent. The average magnetomotive force of one armature coil of a dynamo may be taken to be about 2 per cent. of the magnetomotive force of the field coils, and there is, consequently, a variation of the aggregate magnetomotive force of 2 per cent. when the current in the coil is suddenly reversed.

In the case of a motor it has been shown that commutation tends to reduce the magnetic flux, but owing to the hysteresis of the iron the reduction of flux is inconsiderable, and there is little sparking even if the brushes have no trail. This fact enables motors to be run in either direction without movement of the brushes, which are fixed in the neutral position.

In the case of a dynamo, on the other hand, supposing the brushes to have no lead, the effect of commutation is to increase the aggregate magnetomotive force of the field and armature coils. An increase in the aggregate magnetomotive force will produce a comparable increase in the magnetic flux. Variation in the flux produces sparking. Hence, in the case of dynamos, special arrangements are necessary for the commutation of the current, *e.g.*, the brushes have a lead so as to bring the commutated coils within the magnetic fringe of the leading horns of the magnets, or special reversing connections are provided, as in the Sayers dynamo, to effect the commutation.

ARC LAMP DESIGN.*

BY WM. A. TURBAYNE.

Although the arc lamp is to-day one of the most important pieces of electrical mechanism, yet it undoubtedly receives less attention from an engineering standpoint than any other like device of equal commercial value; this can hardly be accounted for, as the arc lamp field is certainly a very interesting one.

Although numerous experimenters have devoted their attention to the physical properties of the arc, such, for instance, as its counter-E.M.F. and temperature, but few have dealt with the more practical side of the problem, viz., the best method of feeding the carbons, and general design, including guiding statistics of faults to be eliminated, and such other things as would be a help to the electrical engineering profession.

Probably this partially accounts for the small number of arc lamp manufacturers as compared with manufacturers of motors, dynamos, &c., as, in the latter case well-seasoned rules and formulæ are laid down as a foundation; whereas, in the former case one has but to notice faults, if any, in present forms of apparatus, and experiment until improved modifications are a result. It is thus evident that any such improvements are almost universally due to the labours of each individual manufacturer.

As before stated, in dynamo and motor design, we have infallible rules and mathematical formulæ to assist, so that we know beforehand what to expect from the finished machine; but not so in arc lamp design, as each individual make of lamp requires a special controlling arrangement. There are no special rules to follow as regards the resistance or number of ampere turns required for this regulating magnet; these must be suited and proportioned to the other features of the mechanism; neither are there any definite ratios of series to shunt coils as regards their respective resistances or strengths.

It also depends upon conditions whether solenoids or electromagnets with stationary iron cores be used to the best advantage; the former are generally preferable on account of their wider range of steady movement, although in using the latter good results in this direction may be obtained by using properly shaped pole-faces and armatures. A greater strength of field would result for an equal expenditure of energy, although this would seem to be a matter of little importance in an arc lamp, as but a small fraction of the total current is utilised for regulation, and by the use of a leverage this may be still further reduced as the distance from fulcrum to magnet increases.

In the matter of efficiency or preference of design between a differential and non-differential feed, the latter is undoubtedly the better on account of its ability to operate steadily, irrespective of the current strength, the main current having nothing whatever to do with the regulation, and in this respect doing away with short hissing arcs, or "pumping," due to weak or strong currents.

For constant-current working, however, the form of lamp should contain a device to allow carbons to come together after burning, or to place a low-resistance shunt around the same, for, were the carbons all raised and nothing but the high-resistance shunts in circuit, the dynamo would fail to produce current, being a series-wound machine. For constant potential working this is of lesser importance, as the initial E.M.F. is greater than that ordinarily required by the shunts during operation; although a cut-out should be provided to open the shunt circuit and prevent overheating should the carbons be consumed or fail to feed.

No distinction is made in this article between rack or clutch-feed lamps, or lamps wherein the carbons are fed by the unwinding of a metallic band or chain, as these are all but subdivisions of one general principle, and the electrical features of all are identical and subject to the same rules. They all, undoubtedly, have their points of excellence, but any of the above-mentioned forms may be constructed so as to burn very steadily indeed.

A lamp should be designed so as to burn with a practically uniform length of arc, from time of lighting until extinguishing, and afford as constant a light as possible during operation. The writer has noticed arc lamps which, when started, would burn with a short arc, but if left for a length of time would be found to have a long flaming arc; on investigation the shunt coils were found to be exceedingly hot, and according to the well-known law, the resistance increased with the heating, which in turn diminished their attractive power, by lessening the current, and allowed the difference of potential at the carbon points to equal that at the shunt-coil terminals. This, of course, results in a very unsatisfactory light, and should be religiously guarded against.

Another instance of similar nature was that of an arc lamp originally trimmed with heavy carbons and adjusted at the time to burn an arc of normal length, but when the carbons were greatly reduced the arc was of considerable length.

These defects in design are more noticeable in series arc working where the machine allows for increase of voltage, but in constant potential working, as on incandescent or railway circuits, they are of lesser moment, if the lamps are of the differential type, as the weakening of the current, due to the increasing lengths of arc, would reinforce the shunt coils partially by decreasing the action of the series magnets, thus compensating in a measure for the faults mentioned.

In a properly-designed arc lamp, however, faults like the above should not appear, as the resistance of the shunt coils should be high enough to prevent undue heating, and the mode of suspension of the carbons and the internal arrangements should be such as would be affected but little by the gradual decrease in weight due to the consumption of the carbon. For this same reason a lamp should be adjusted for length of arc when about to feed, as then the whole weight of carbon and rod is about to be released from its support.

To sum up, the best foundation design for an arc lamp for direct-current working would undoubtedly be that of the non-differential variety, with proper cut-out and mechanical details, and in which faults, as before mentioned, would be totally left behind.

For alternating-current working the conditions are different. In this case the arc should be formed as slowly as is practical between carbons of equal length or their equivalent, all magnet cores should be carefully laminated, and any closed secondaries which would be likely to be used, as, for instance, metal magnet spools, should be broken up to prevent heating and other efficiency-reducing losses.

In conclusion, it is to be hoped that more work of investigation may be done in this line by persons having time and means at their disposal, and their labours recorded, in order that all interested in this important branch shall be benefited.

* From the *Electrical Engineer*, of New York.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, December 8th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. The following Papers will be read: (1) "A Potentiometer for Alternating Currents," by J. Swinburne. (2) "The Specific Resistance of Sea Water," by W. H. Preece, F.R.S. (3) "The Calculation of the Coefficient of Self-induction of a Circular Current of a given Cross Section and Aperture." (4) "The Magnetic Field of a Cylindrical Coil," by Prof. G. M. Minchin, M.A.

TUESDAY, December 12th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. "Cask-making Machinery," by Mr. Lewis H. Ransome.

WEDNESDAY, December 13th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Carriage-way Pavements for Large Cities," by Lewis H. Isaacs.

THURSDAY, December 14th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Annual General Meeting. Reception of the Annual Report of the Council, and the election of Council and Officers for year 1894. Continuation of discussion on "The Electrical Transmission of Power from the Niagara Falls," by Prof. Geo. Forbes, F.R.S.

FRIDAY, December 15th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. "The Brightness of Light: its Nature and Measurement," by Messrs. T. M. Barr and C. E. S. Phillips.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Alternate-Current Electrolysis.—The conclusions to which Dr. J. Hopkinson and Messrs. Wilson and Lydall are led, by their researches into alternate-current electrolysis, are summed up in their recent Paper before the Royal Society in the following terms:—"A general conclusion of the experiments is that about one-tenth of a coulomb suffices to fully polarise 150 sq. cm. of platinum. This will liberate 0·00001 of a gramme of hydrogen; hence 0·000,000,07 gramme of hydrogen serves to polarise 1 sq. cm. of platinum. 0·000,000,07 cm. is probably a magnitude comparable with the distance between molecules of hydrogen when this body is compressed to a density comparable with the density of liquids."

The Electrician.

(The Oldest Electrical Journal.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :
1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.
Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.

Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same book in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

SCIENTIFIC SOCIETY EVOLUTION.

All establishments, it has been said, die of dignity, being too proud to think themselves ill and to take a little physic like ordinary mortals. In these days it is rather to be feared that our institutions will kill themselves with physic. The spirit of compromise, that is to say, the spirit which seeks to patch up, paint over, and make nice is, apparently, infectious. The *doyen* of our scientific societies having been solemnly warned in the columns of *The Times* that unless it moves with the age, and that smartly, we shall see what we shall see, immediately proceeds to indulge in a little introspective investigation, the outcome of which is a determination to make its meetings "not only interesting, but, if possible, amusing," and to provide to that end better lantern apparatus. We cannot help thinking that competition in this matter with its near neighbour (the Royal Institution) is to be deprecated. If the anonymous correspondent of *The Times* must be mollified by a little painting up and patching over it is, on his own showing, evidently not this particular kind which will attain that much-to-be-desired end. But, in truth, is it necessary that any Papers at all should be read before the Royal Society, or that it should condescend to compete for them? If the functions of the Royal Society were confined to making a graceful and world-valued recognition of the work of labourers in the field of science, to aiding by the funds at its disposal the work of deserving experimenters, and to publishing in the best possible manner, and at a reasonable price, valuable scientific researches which would otherwise never see the light of day, or would remain scattered amongst the volumes of half-a-dozen different societies; if the Royal Society, we say, were to do this, and nothing more, it would deserve well of the commonwealth of science, and its

prestige, so dear to all Englishmen, would suffer no abatement. The President, Council, and Fellows are, however, no doubt, alive to the necessities of the situation, and our fear is not that they will allow the Royal Society to die of dignity, but that in their desire to be all things to all men, they will discover disease where none exists, and try to amuse where they had better not try.

But the cry for innovation is not confined to the Royal Society nor to England, and in the case of the lesser lights of the scientific firmament the alterations called for are as often as not very easily effected, and meet a decided want. Thus, in his last letter, our New York correspondent was able to announce that the American Institute of Electrical Engineers had finally adopted a long-contemplated scheme providing for local meetings. Upon the application of twenty members residing in any locality the Council may authorise the holding of local meetings, at which Papers accepted by the Institute, and only such Papers, may be read and discussed simultaneously with, or subsequent to, a meeting for the same purpose in New York, no publication of Papers or discussions being, as a rule, permitted, except in the *Transactions* of the Institute. This scheme is the logical outcome of living in a country as big as a continent. With us eight or ten hours in the train suffice to bring a member eager to participate in dinner or discussion from the uttermost parts of our diminutive land. But in America, where no city dare lay claim to an independent existence unless it be at least a thousand miles from everywhere, and where trains hasten slowly, an Institute located in the extreme east is beyond the reach of electrical engineers residing in the west, south or centre. Even in England, members living in London get more value for their annual subscription to the Institution of Electrical Engineers than those whose duties keep them further afield; in the States the magnificent distances render a system of local meetings like that described by our New York correspondent absolutely essential, unless the American Institute of Electrical Engineers is to be such only in name.

In England, therefore, the need for planting local shoots from our engineering and kindred institutions is not, from the point of view of mere distance, particularly pressing. The idea, nevertheless, possesses one signal advantage which would render its adoption at home advisable. It would tend to check the multiplication of local societies, with their appalling multiplicity of *Proceedings* and *Transactions*. Any scheme which promises to keep down the flood of printed matter, and to concentrate its flow into a single channel, deserves consideration. The idea of local meetings is not, of course, new, nor confined to America. The Society of Chemical Industry has its Liverpool, Manchester, Newcastle, and Nottingham sections, which hold their own meetings with as much ceremony and effect as the London section in Burlington House. The Institution of Mechanical Engineers also meet regularly in the provinces. The majority of our societies, scientific, engineering, and other, are, however, content to cover all England in title only, and to remain, in fact, almost purely metropolitan bodies. This narrowing of their spheres of influence is probably largely responsible for the unnecessary calling into existence of many a local society, with its office bearers, secretary, and obscure journal. Only within the last few weeks, for instance, a Northern Society of Electrical Engineers has blossomed forth, its *raison d'être* being to afford electrical engineers resident in and about Manchester opportunities for discussing matters of professional interest. Much can without doubt be said in favour of local societies, and it is only their undue multiplication that we deprecate. Indeed the number, variety, and individualism of local societies in this country inclines one to the belief that there must have been at work some scientific analogue of the Abbé Sieyès, who, we are told, had whole nests of pigeon-holes full of constitutions, ready made, ticketed, sorted, and numbered; some with councils of elders and councils of youngsters, some without any councils at all; so that no one should go unsuited from his shop. We do not, of course, suggest the local-meeting idea as a panacea for all the ills the constitution of a scientific or engineering body is heir to; but a well-considered scheme of local meetings would, we think, if vigorously pushed, widen the scope and freshen the life of many a society; and, above all, would have a marked tendency to convert a single publication into a recognised receptacle, not for rubbish, but for the best work relating to that particular branch of learning or engineering with which the society is connected.

OBITUARY.

PROFESSOR TYNDALL.

It is a sad moment when one is called upon to take up one's pen to write an obituary notice of a master at whose feet one has sat, and from whose work and words one has received instruction, counsel, and inspiration in one's life work. John Tyndall was one of those men to whom it was given, not so much to be himself pioneer as to diffuse into others the spirit of pioneering, not so much to investigate as to make known the investigations of others in a spirit of sympathetic enthusiasm that warmed and infected his hearers. Possessed of a fluent and impressive delivery, rising at times into real oratorical power, his lectures attained a charm of style unique and inimitable. Ease and skill in experimentation before an audience—an art only to be acquired as the result of skill practised in the laboratory—he probably learned more from Faraday than from any other, except, perhaps, Bunsen. Even in his less-convincing discourse, when he left the exposition of science for the speculations of the philosopher, his peculiar gifts of manner carried his hearers irresistibly along. So great was this charm of animated personality that his own immediate generation ranked him, in consequence, more highly than his undoubtedly great achievements in research will seem to the generation following to have warranted. Twenty years ago his name was continually linked, in the public voice, with that of Darwin as of coequals in science. Few would to-day claim for Tyndall so high a pedestal of fame.

Born near Carlow, in 1820, the son of a member of the Irish constabulary, he had few advantages in the way of early training beyond a sound knowledge of geometry, and a schooling that lasted until he was nearly nineteen. He once remarked to the writer that he would not have missed the training in exact thought afforded by the propositions of Euclid, for all the more directly mathematical training in the world. He entered the Ordnance survey as a civil assistant in 1839, and was occupied in this work until 1843. Then, for three years, he was employed in railway surveying in various parts of England, only to find that his passion for science would not let him settle to the life of surveyor. So he accepted a post as assistant teacher at Queenwood College in Hampshire, and was by that fortunate circumstance brought into fellowship with the then rising young chemist, Edward Frankland. In 1848, these two young men repaired to the Marburg to study under Bunsen, Tyndall going on later to Berlin to work under Magnus at physics. He translated Clausius's thesis on the moving force of heat, and subsequently that of Helmholtz on the conservation of force, which was pointed out to him by his friend Du Bois Reymond. Whilst in Germany he began those investigations into diamagnetism and the relations of magnetism to crystallography which will ever be associated with his name. It was his work on these two kindred

Digitized by Google

topics that brought him first into notice. He was, on his return to England, invited to lecture at the Royal Institution, where Faraday had for twenty years been actively at work. The lecture was given in February, 1853, and in May of the same year the post of Professor of Natural Philosophy was created for him. He devoted much time during the succeeding years to research, and from magnetism passed on to the subject of the radiation of heat, upon which subject he published—mainly in the *Philosophical Transactions* of the Royal Society—a number of memoirs. The substance of these was afterwards reprinted in a separate volume. His more popular work, "Heat a Mode of Motion," was published in 1863, and was followed by the volumes of lectures "On Sound" and "On Light." This latter was the substance of his famous lectures delivered in America in 1872. On electrical subjects, beyond the diamagnetic researches, he published little, his "Notes on Electricity" being mainly historical. His other topics of research were: the motion and structure of glaciers, the spread of dust and germs in the atmosphere, and the effect of mist and fog on sound.

No account of Tyndall would be faithful which did not contain some reference to the numerous controversies which he entered into with various scientific men. He was an uncompromising, and, at times, even bitter, adversary, and even on the most purely scientific topics could scarcely argue without personal tone. His dispute with J. D. Forbes on the origin of glacial motion, and that with Prof. Tait as to the merits of Robert Mayer as the founder, rather than Joule, of the dynamical theory of heat, witness to this personal trait. His controversy with Prof. W. Thomson (now Lord Kelvin) on the subject of diamagnetic polarity was a curious episode, since the opinion that seems to have been held at the time that Tyndall had answered his critic's strictures would not now be sustained by any competent authority. Tyndall took the view that the apparent repulsion of a bar of bismuth from the pole of a magnet was due to the induction of some new polarity, the opposite of that which would have been the case if the bar had been of iron. The north pole of a magnet induces, he maintained, a north pole in the end of the bismuth bar that is presented to it, and therefore repels it. Thomson on the other hand, maintained that the polarity induced in the bismuth was identical in direction with that in any other substance, but that the amount of the induction differed with the relative permeability of the substance and of the surrounding medium. As a consequence there was a tendency for the bismuth to move from the denser regions of the magnetic field into the less dense. The phenomenon was just as truly in accordance with the law of magnetic attraction as the apparent repulsion of a balloon from the earth is in accordance with the law of gravitation.

Tyndall's attitude towards the exponents of orthodox Christianity, and his utterances on the subjects of miracles and of the efficacy of prayer, raised, twenty years ago, a storm of theological opposition which had scarcely died away before his retirement into private life in 1887. For several years previously it was evident that his powers were waning. The repose of his last years in the solitudes of Hindhead, or of Bel Alp was only broken by his excursions into political warfare. His sternly independent spirit broke out impetuously in diatribes that caused his friends no little regret. Unfortunately, he was not the only man of science who, on one side or other of the Home Rule quarrel, showed how party strife may upset the balance of judgment.

In his youth the disciple, and in his middle age the intimate friend, of Carlyle, he also owed much to the influence of Emerson and to that of Goethe. His lectures contain frequent references to these his masters in literature; but his style was not modelled on that of any of them. His biography of Faraday was a thoroughly sympathetic work, though he differed widely from Faraday in religious views. The vehemence with which at times he spoke and wrote was indeed but one result of the passionate sincerity of soul and of the restless energy that burned within him. He made the whole world his debtor by his masterly expositions of modern science, and the whole world may well forgive the exuberances of his ardent nature. S. P. T.

COMPARATIVE COST OF LIGHTING BY GAS AND BY ELECTRIC LIGHT.

On April 8, 1892, Prof. Ayrton gave a discourse at the Royal Institution on meters, motors, and money matters. He exhibited on that occasion several curves, showing the cost of lighting by different gas burners. These curves, which have not before been published, are combined in a single diagram in Fig. 1. The cost is based upon one candle-power for a year, at four hours a day, and gas at 2s. 6d. per thousand cubic feet. This comes to 1,460 hours, and is equivalent to lighting from dusk until 10 p.m.

The costs have been derived from the figures in the Report by Messrs. Haycraft, Weightman and Gawthorp upon Test of Gas Burners, an abstract of which has appeared in our last two issues.

In attempting to draw a comparison between the cost of gas lighting and of electric lighting we are met with two difficulties. The candle-power per cubic foot of gas per hour, called the efficiency, in the Report to which we have alluded, depends largely on the size of the burner. Small gas burners give a very poor result. No such difference exists with glow lamps. It is true that the 8-c.p. 100-volt lamp of the Edison and Swan United Company took about 5 watts per candle, and that we are now hoping to find 2½ watt lamps, or at all events lamps taking a mean of about 3 watts per candle throughout their lives; but speaking generally, the efficiency of a glow lamp has little to do with its candle-power, as with gas burners. On the other hand, a good gas burner supplied with decent gas and not exposed to dirt and weather, has a long life, and the candle-power remains practically unaltered. It is true that gas burners often become choked with dirt and rust, greatly reducing the light, but this cannot be fairly attributed to any defect in the burner. A glow lamp suffers from such a defect. Its life is short and uncertain; more figures must be based upon its average performance, and the cost of renewals must be added to the cost of electrical supply.

While for purposes of strict comparison we ought to consider the mean performance it must be admitted that in a large majority of cases the consumption of current per lamp is of more importance to the consumer than the watts per candle-power. We could at one time get no 100-volt lamp that took less than an average of 30 to 40 watts throughout its life, and now we can buy lamps starting at 20 watts. As we recently observed, a 4-c.p. 100-volt lamp, taking, say, 12 watts to start with, would be a great boon to consumers, and would not, we believe, entail a loss of revenue to supply companies. A small gas burner, however, is a distinctly wasteful affair, as is clear from curve 7, Fig. 3, and curves 7 and 8 in Fig. 5, on page 96 of our issue of November 24th. And it must be remembered that the Welsbach burner has a short life, a quickly falling candle-power, and that the mantle is extremely fragile.

After these preliminary remarks we may proceed to Prof. Ayrton's curves. Four different burners were selected, and the chief feature of the diagram, Fig. 1, is the quality of the regulation. The Bray's street burner regulates perfectly between 0·6in. and 3in. pressure. This is very interesting; but it must be remembered that gas companies, with all their failings, do not force their gas through the consumers' pipes at 3in. pressure. For practical purposes, pressures from 0·6in. to 1·5in. only need be considered. We have no hesitation in disregarding at once the Argand burner; it is as outside the present comparison as an arc lamp. We assume 1s. 10d. as the average cost. We do not, however, take this figure from the curves in Fig. 1.

The last tables of the Report on Tests of Gas Burners consisted of the cost of one candle-hour at the maximum observed candle-power, with different burners, gas being taken at 2s. 6d. per 1,000ft., and the cost of one candle-hour under the conditions of maximum efficiency. Omitting the last six burners, which are of large candle-power and high efficiency, the average of the remaining 22 is 0·0187 for the maximum candle-power, and 0·0156 for the maximum efficiency. The maximum candle-power necessitated in most cases a high pressure of gas. We therefore take the mean candle-power at the maximum

efficiency at whatever pressure that efficiency may be obtained. A cost of 0·0156 an hour for 1,460 hours (Prof. Ayrton's unit) comes to 22·8d., or, say, 1s. 11d.

Before proceeding further, it may be remarked that the cost of electrical supply for glow lamps at 2½ watts per candle, and at 6d. per supply unit is exactly the same as this average, viz., 1s. 10d. for 1,460 candle-hours. To this lamp renewals must be added.

Lamp renewals at 1s. 6d. per lamp, and a life of 400 hours, comes to about 5s. 6d. for 1,460 hours, or 7s. 4d. for a life of 300 hours. In the absence of any definite information, we will assume a life entailing a cost of 6s. for renewals during the year. But as 8-c.p. lamps cost no less than 16-c.p. lamps, and may be assumed to have the same life, the lamp renewals for the 8-c.p. lamps is twice that of 16-c.p. lamps per candle-hour or candle-year. The cost for 1,460 candle-hours would be as follows:—

	2·5 watts per c.p.	3 watts per c.p.	4 watts per c.p.
1c.p. without renewals	21·9d.	26·28d.	35.04d.
8 c.p. with renewals	30·9	35·28	44·04
16 c.p. with renewals	26·4	30·78	39·54

From these examples we must for the present discard the 2·5 watts per candle. It is true that we have promises, and indeed offers, of such lamps, and a guarantee of one, at 2s.; but we have no experience as to their life. We take, then, 3s. as a fair average, and against this we put the 1s. 10d., the average cost of gas lighting. The cost of electric light by glow lamps at 6d. per unit is, then, to the cost of gas lighting at 2s. 6d. per thousand as 100 is to 61. The two costs would be almost identical if the price of gas were 4s. per thousand. The old rule used to be to multiply the price per unit of electrical supply by 10 to obtain the equivalent price of gas per thousand cubic feet. It appears that at 3 watts per candle and lamp renewals, at the rate we have assumed, the factor 8 instead of 10 may be used.

We have assumed that the cost of renewals will be 6s. for 1,460 hours, irrespective of the watts per candle at which the lamps are run. The renewals will of course be much lighter for lamps at 4 watts per candle than 2½ watts, say 3½ to 4 times less, but we have no data to go upon at present. This will tend to equalise the costs of electric lighting; but as we have taken such short lives as from 300 to 400 hours, the result will be to reduce the costs of the lighting at 4 watts per candle, and probably not to increase even the lighting at 2½

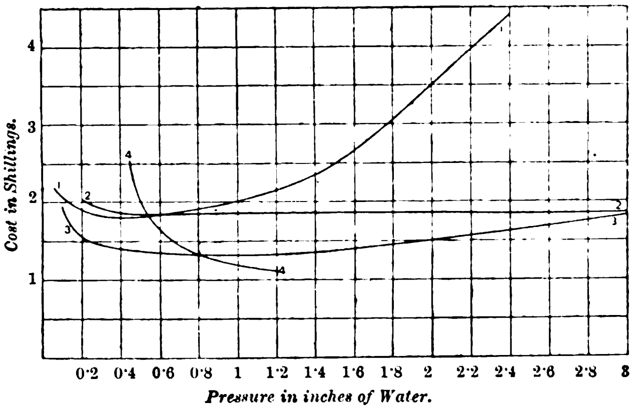

FIG. 1.—Pressure, and Cost in Shillings per Candle per Year, burning four hours per day, at 2s. 6d. per 1,000 cubic feet.

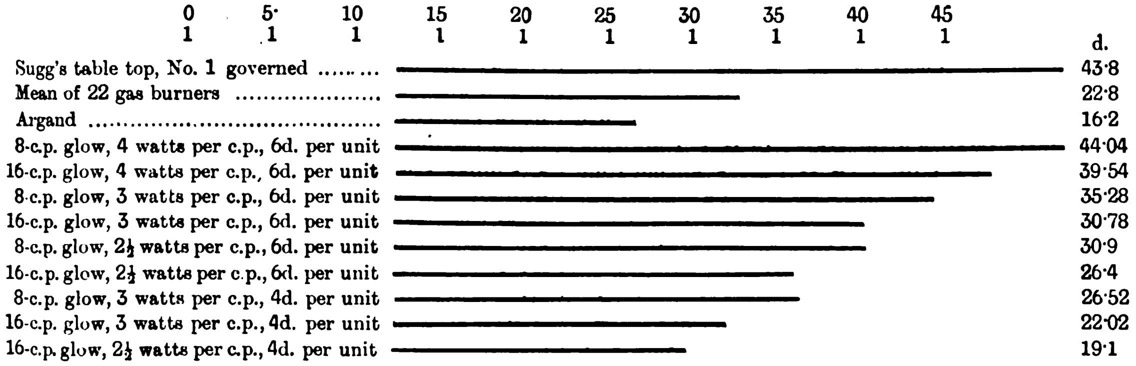
1. Bray's Enamel Regulator, No. 5, Union Jet.
2. Bray's Burner for Street Lamps, with Governor.
3. Sugg's No. 5, Table Top, Governed.
4. London Argand (Sugg's No. 1).

watts to any appreciable extent. It appears that in order to compete with the average gas burner with gas at 2s. 6d. a 16-c.p. lamp must be run at nearly 2½ watts per candle and at the rate of 5d. per unit for electrical supply.

The following table shows at a glance the comparative magnitudes of the foregoing costs. We are indebted to Messrs. R. J. Wood and H. C. Leake, of the Central Institution, for confirming our numerical calculations.

Comparison of Costs of Lighting.

Scale:—One centimetre equals 5d. per candle per year, four hours per day.



It should be noted that the difference between the costs of 16-c.p. and of 8-c.p. lamps, other things being equal, is the cost of renewals of a 16 c.p. lamp.

ON THE ELONGATION PRODUCED IN SOFT IRON BY MAGNETISM.*

BY SIDNEY J. LOCHNER.

Had it not been for recent experiments by M. Alfonse Berget,† which apparently contradicted those of Mr. Shelford Bidwell,‡ I should have deemed it a waste of energy to have attempted to contribute anything further to our knowledge of the subject. My original purpose was to confirm the experiments of either one or the other, not expecting in any way to reconcile the two. But I am led to believe that I have in general verified the experimental results of both.

The instrument which I employed for this investigation is in its essential features a Michelson interferential refractometer. With this instrument I found it an easy matter to measure to a tenth of a fringe, which means about $\frac{1}{1000000}$ of an inch. In making these observations, the only difficulty which I found at all troublesome were certain effects due to hysteresis.

Mr. Shelford Bidwell, in mentioning the difficulties which he encountered, states that he found it absolutely necessary to centre the bar in the coil. He finally adopted the method of suspending the coil on one end of his bar, so that it moved with the bar. In this way the effect was entirely obviated.

Early in the experiment I found that for a given magnetic field I could produce different amounts of expansion, depending upon the manner in which the current had been applied—for instance, whether the full amount of the current had been turned on suddenly or, on the other hand, had been applied

* Abstract from the *Phil. Mag.*, Vol. XXXVI, No. 223.
† *Comptes Rendus*, November 7, 1892.
‡ *Proc. Roy. Soc.*, Vol. XL.

Digitized by Google

gradually; then, again, whether the current had been gradually *increased* from zero, or had been *decreased* from a higher point.

If the current be gradually increased from zero up, at a certain point we reach a maximum amount of expansion: now a further increase in current will produce a decrease from that maximum; but if, on the other hand, we gradually decrease the current, we are able to obtain a still greater expansion. This increase in the case of soft iron is from 0·05 to 0·20 of the total amount of expansion otherwise obtained. Mr. Bidwell has noted a peculiarity in the behaviour of a steel bar which will come under this head. At lower points in the expansion this peculiarity does not seem to exist.

I have adopted, as the method which gives the most uniform and certain results, that of quickly but gradually *increasing* my currents (not using the first contact), counting my fringes from the zero point for my lighter currents and from the turning, or maximum, point for my heavier currents. For attaining this end I constructed a resistance out of fine platinum wire placed in water to prevent fusing, with a sliding metallic contact. By using this resistance directly, and as a shunt for the smaller currents, I have been able to have the current perfectly under control.

In order to determine the effect of the thickness of his bar upon the amount of expansion, Mr. Bidwell selects for the purpose three rods of 100mm. length and 2·65, 3·65, and 6·25mm. in diameter. He assumes that the iron in the three bars may be regarded as similar, and that the differences in the expression are due only to their diameters. He finds that the expansion "varies inversely as the square root of the diameter" (the length remaining the same). I regret to say that my results do not in any way confirm his conclusions. Instead of finding that larger bars give less expansion than smaller bars, I find just the opposite. At first I thought that the best way

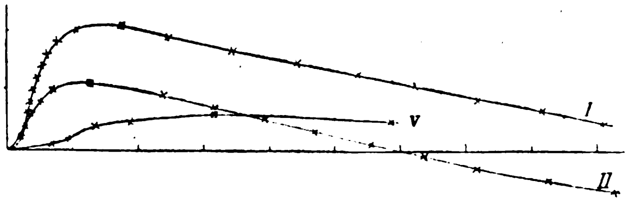


Fig. 1.

to make this test would be to take my largest bar and turn it down to successively smaller diameters. In fact, I did this. The resultant bar showed a falling off of the expansion from 10·3 fringes to 7·2 fringes. I found it a very difficult matter to turn so long a bar perfectly true in the lathe which I had at my disposal; and at the same time I was not certain about the effect of the strains due to the turning. Further, there was no certainty that the inside of my bar would behave in the same manner as the outside.

Although I have quoted M. Alfonse Berget's single experiment, because the ratio in this case was exceedingly large, yet, as the length of his bar was so short, and as he tells us nothing as to whether he has given us the elongation from the first or second contact, one must feel compelled to give it little weight except for showing the main point in the discussion. It must also be borne in mind that the iron used by different observers could of itself produce variations of as much as 25 per cent., due to a difference of permeability.

It may be stated briefly that my observations furnish the following evidence in regard to the expansion which takes place in soft-iron bars:—

1st. They confirm the general form of Mr. Shelford Bidwell's curves.

2nd. They indicate that the expansion is a function of the ratio between the diameter and length, and that the elongation varies *directly* as possibly the square root of this ratio.

3rd. They further indicate that the expansion varies directly as the permeability.

4th. That the amount of current required to produce the maximum expansion, and also the point of no expansion, likewise depends upon the ratio between the diameter and length.

5th. That there are two maxima: one produced by increasing the current, another by decreasing the current from that point which produced the first maximum.

6th. They confirm Prof. A. M. Mayer's observations, that the first contact gives more expansion than the second and following contacts, and, further, even these seem to disagree slightly among themselves, the expansion falling off with subsequent contacts.

In Fig. 1 I have plotted the expansion curves of three of the bars which show the greatest differences.

Mr. Bidwell's curves are similar in form to those produced by Bars I. and II., while M. Alfonse Berget's curve, as would be expected, agrees more closely in form with that of Bar V.

The experiments were carried on in the physical laboratory of Clark University, under the direction of Prof. A. G. Webster, to whom acknowledgment should be made for frequent suggestions.

THE REFLECTION OF ELECTROMAGNETIC WAVES AT THE END OF A CONDUCTING WIRE.

In *The Electrician* for April 28, 1893, p. 734, we alluded to some theoretical work of MM. Birkeland and Sarasin, appearing in the *Comptes Rendus* a few days previously, and consisting of an important application of Poynting's energy theorem to the case of a Hertz oscillator. They considered the movement of energy in the field, and how its rate of subsidence was affected by the presence of neighbouring conductors; and succeeded in giving a plausible explanation of a curious experimental result, obtained by MM. Sarasin and De la Rive, viz., that the stationary waves, formed by reflection at the end of a wire, have their nodes differently situated according as the waves are electric or magnetic. In the *Comptes Rendus* for November 6th, MM. Birkeland and Sarasin publish a further communication on this subject. It consists of a description of some experiments made with the object of exploring the field in the neighbourhood of the end of the wire by means of little resonators varying in diameter from 10 to 25 centimetres. The experiments do not confirm in every respect the views previously advocated by the authors, but they certainly form an important experimental contribution to the remarkable energy theorem of Prof. Poynting.

The electric undulations were produced by a small Hertz plate oscillator, giving sparks about 3 mm. long, the sparks being produced in oil. Facing one of the primary plates was a similar secondary plate attached to a copper tube 1 cm. in diameter and nine metres long. The resonators were in all cases circular, and fixed vertically, with the spark gap at the top. They were capable of two kinds of motion: one a rotation about a vertical axis passing through the spark gap, the other a motion of translation parallel to the copper conductor.

By means of these resonators the authors explored the field in the neighbourhood of seven different parts of the wire, the plane of the resonator in all cases being normal to the wire. Each determination of a node involved at least ten measurements. The numerical results thus obtained for the 10-cm. resonator are given in the Table below. The distance of the resonator from the conductor is counted from the axis of the latter to the nearest point of the former.

Distance of resonator from conducting wire.	2cm.	10cm.	20cm.	30cm.	40cm.	50cm.	60cm.
1st node..................	16·0	15·4	9·5	7·7	1·8	...	..
2nd „	56·4	56·3	54·2	51·5	47·3	44·8	37·7
3rd „	96·5	95·7	95·2	93·5	90·5	88·9	87·5
4th „	135·0	135·8	135·1	134·6	130·8	129·7	130·5
1st internode...........	40·4	40·9	44·7	43·8	45·5	54·6	...
2nd „	40·1	39·4	41·0	42·0	43·2	44·1	49·8
3rd „	38·5	40·1	39·9	41·1	40·3	40·8	43·0

In Fig. 1 the crosses denote the positions of the centre of the 10cm. resonator for the nodes given in the above table. When the 25cm. resonator was used the corresponding positions are indicated by the small circles.

Digitized by Google

These results seem to show that if the first impulse given to the resonator occurs from electro-magnetic motions parallel to the conducting wire, the second must arise by direct radiation from the neighbourhood of the end of the wire. In fact, all the nodes are situated as if the energy, from which is derived the second impulse received by the resonator, travelled quite close to the wire until arriving at the end of the conductor, and then radiated from this point as a centre.

In the second place, the experimenters tried to find how to turn the plane of the resonator about its vertical axis, so that the total effect of the two impulses was a maximum.

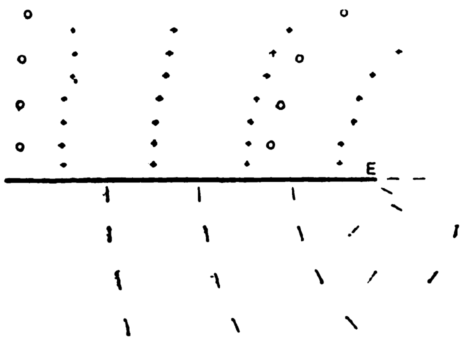

FIG. 1.

These directions are indicated in Fig. 1. They have been determined in most instances for places which are the internodes of the undulations. Two of the directions (indicated by the dotted lines) were, however, taken in positions where the nodes occur. The results strongly indicate radial action proceeding from the end of the wire.

The three series of observations made in the neighbourhood of the internodes shows that the normal to the plane of the resonator nearly bisects the angle between a line drawn parallel to the wire and the radius drawn from the end of it. The two observations made at the nodes show that for the maximum effect it is necessary to so turn the resonator that the electric waves arriving from the end of the wire strike its plane normally.

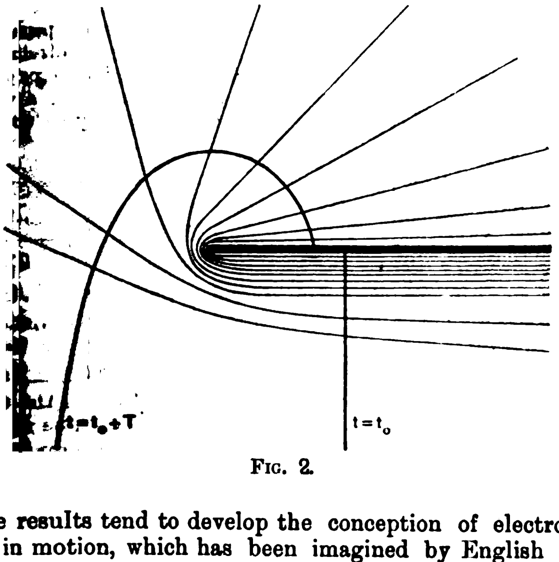

FIG. 2.

The results tend to develop the conception of electrostatic tubes in motion, which has been imagined by English physicists. Suppose that an electrostatic line (of the direct wave), each part of which moves normally to its direction at the moment considered, is rectilinear and perpendicular to the conducting wire. This will not be the case with the reflected wave.

Measurements previously made by one of the investigators show that at the surface of the conducting wire there is not any appreciable lag of the first node, and that in consequence the part of the electric tube in the immediate neighbourhood of the wire makes the complete turn round the end of this without any appreciable retardation. But the distant portions of the tube cannot traverse the same angular distance in such a short interval of time. The tube after reflection accordingly curves round the wire, the distant parts of the tube being shaped something like the tail of a comet (*see* Fig. 2).

Such is the origin of the characteristic radiation, proceeding from the end of the conductor, the existence of which the authors appear to have established. It follows as a matter of course that if, according to Poynting's theorem, the motion of the energy is always perpendicular to the instantaneous direction of the lines, energy must radiate from the end of the wire into surrounding space.

THE CONTINUOUS CURRENT ARC AS A STANDARD OF LIGHT.*

BY ANDRÉ BLONDEL.

(Continued from page 119.)

When it is a question of measuring a single arc lamp, the following method seems capable of yielding practical results.

(i.) The arc lamp is compared with the standard by means of a Foucault or Bunsen photometer, the eyes being blinked, as suggested by M. Allard, until the sensation of colour disappears. In this way one obtains the values of the *luminous* intensity always under identical conditions.

(ii.) The two sources of light are then compared from the point of view of reading by means of photometers based on the visual faculties, care being taken in every case to give the same absolute value to the illumination, and to expressly state it. The best value is such that the observer can only just read ordinary print. In this manner the value of the visual intensity is obtained.

By means of these two measurements,† both easily made, and without the intervention of coloured screens, we have measured the light under the two extreme conditions in which it is employed, that is to say, under those which it is of the most practical interest to know. It does not much matter whether we know the value of a light exactly when it is more abundant than necessary. The essential thing is to know what is the maximum useful light it can furnish. This once known, the effect of the Purkinje phenomenon no longer causes the same disadvantages as is the case with existing methods. Nevertheless, it seems decidedly better in the photometry of arc lights to replace existing standards by a secondary standard, also having the arc as origin, so that we may have two almost identical tints.‡ In that case it would only be necessary to ascertain once for all the properties of this standard to gain an accurate idea of the values of lamps measured against it. This standard§ is obtained, as I have said above, by isolating a small portion of the positive crater of carbon of sufficient purity.

I will not in this Paper describe the apparatus in its first shape.‖ I will only add two remarks to my original description, remarks which have been suggested to me by further experiments.

(i.) The little hole in the cold diaphragm placed close to the arc becomes filled at the end of a short time by carbon dust, due to the condensed vapour. It is, therefore, necessary to use fairly large holes, and to clean them out from time to time. Unless this is done errors will arise.¶

(ii.) The flame passing before the crater may, as Abney says,** apparently alter its intrinsic brilliancy. This defect, as well as those due to air currents, may be obviated by a new device which I now have, and which consists of an arc lamp with horizontal carbons, the arc of which is enclosed in a very small electric furnace, similar to those of MM. Violle and Moissan, but of simpler construction. This is shown in Fig. 3. The device will, I think, give more constant results than those obtained with the first type of apparatus. I will not insist further upon the necessity of having as high a current density as possible, so that the crater may be well "saturated."

* Paper read before the International Electrical Congress at Chicago, August, 1893.

† It would also be a good thing to make a measurement with a coloured screen absorbing the blue and violet rays, in order to get an idea of the value of the lamp in time of fog. It is well known that the electric light then loses many of its advantages.

‡ The tint of a lamp is always slightly less white than that of the standard, because the latter only uses the most incandescent part of the arc. But this difference, which is indeed scarcely perceptible, is no objection to this standard.

§ Constructed by Werlein, optician, Paris.

‖ Vide *The Electrician*, Vol. XXX., p. 658, April 7, 1893.

¶ From this point of view it may, perhaps, be better to use, instead of a hole, a lens of known surface, the coefficient (k) of which could be previously measured. The light produced on the photometer by the carbon image is, in fact, proportional to the surface (s) of the lens and to the intrinsic brilliancy i; $c = k\,s\,i$. The lens could be placed much further from the arc, and the water-jacket could be suppressed.

Experiments.

I undertook a series of experiments with a view of comparing the intrinsic brilliancies of different carbons, either against each other or against an ordinary standard. In the first case I set two similar arc standards* up at either end of the photometer bench. In the second case, I merely compared an arc standard with a Carcel lamp, or I made a measurement with a Mascart photometer with petroleum standard.

This very simple method is the only one which can inspire complete confidence, since it enables one to investigate the phenomenon directly, and is more sensitive than any complex instrument; it enabled me to detect very important differences that were absolutely inappreciable on the pyrophotometer, which is not very sensitive under such conditions. Moreover, by setting two arcs against each other all the different errors resulting from difference of colour disappear.

The experiments were carried out at the Laboratoire Central d'Électricité (Paris), with the assistance of MM. Guilbert and Perrin. It was M. Perrin, Chef des Travaux Pratiques du Laboratoire, who was good enough to undertake the Bunsen photometer readings, which he accomplished with remarkable accuracy. Experi-

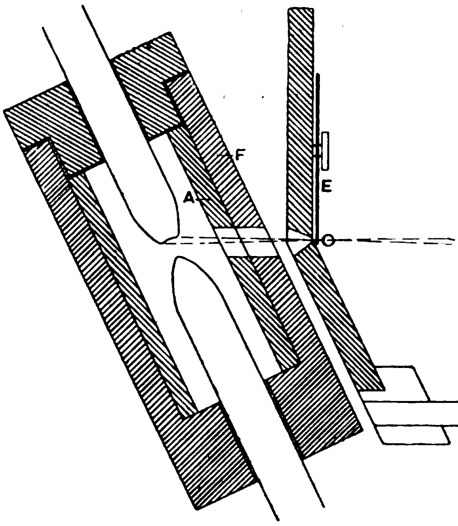

Fig. 3.

ments were carried out on three different makes of carbons, which I will denote by the letters B, C, L; some were homogeneous, others were soft, others again were hard, some had a more or less conducting core.

Constancy of the Brilliancy of a given Carbon under Constant Conditions.

When carbons of bad quality are employed, especially very hard uncored carbons, the brilliant part of the crater is continually moving, and it is difficult to make use of the arc as a standard. On the other hand, if suitable picked carbons are used, and the current densities indicated by me are employed, then it is possible to obtain great uniformity and fixity in the brilliancy of the crater. If the crater is examined on the hundred-fold projection afforded by the lens, it has the aspect of a boiling mass covered with little bubbles, which are generated and which burst without ceasing. But these bubbles are no longer seen when the lens is replaced by the pin-hole screen, and they are, moreover, much too small compared with the photometric surface of a Bunsen screen to in any way inconvenience the observer, or to compromise the accuracy of the measurements. In fact, with *good carbons*, the illumination of the photometric surface is remarkably constant, and all the comparisons showed this method of "diaphragmation" is quite correct enough for a standard.

As a sample I give below a series of measurements made without special precautions, the light of the crater of a 10mm. 20 ampere carbon being compared with the light of a carcel.

Table I.—*Total length of the photometer bar 3690mm. distance from the photometer screen to the standard carcel.*

Readings.	Average.	Differences.
790	794·5	4·5
804		−9·5
790		4·5
794		0·5

* I take this opportunity of expressing my thanks to MM. Sautter et Harlé, who, for the purpose of these experiments, lent me two of their excellent projectors.

This shows a relative error of 1 to 3 per cent. Generally speaking, therefore, one could with good carbons attain an accuracy of from 2 to 3 per cent., which is quite sufficient for arc measurements.

I may remark in passing that the boiling appearance of the crater seems to be a corroboration of the theory of the volatilisation of the carbon.

Constancy of the Brilliancy of a given Carbon under Varying Conditions.

M. Violle having showed that the brilliancy of a carbon is independent of the current and pressure, and Abney having arrived at a similar conclusion, I have not thought it necessary to take the question up again, but I will observe that the proof given by M. Violle only applies to the *maximum* brilliancy and to a permanent current and pressure. In fact it is easy to state the two following facts:—

(i.) The average brilliancy of the incandescent portions, taken as a whole, as measured for instance in lighthouse lights, increases with the current;* it increases also with the density of the current until the crater is well "saturated."

(ii.) If, by means of a rheostat, for instance, we suddenly vary the value of the current of a lamp, the intrinsic brilliancy undergoes a temporary and very appreciable variation, which may reach 10 per cent., and which diminishes gradually until the dimensions of the crater are so altered as to restore the surface of emission to the value which it ought to have having regard to the new value of the current.

This phenomenon is easily explained when we remember that the heating of the positive crater only takes place at the surface of passage, and that the temperature of volatiliation is therefore only reached by a very thin superficial film. This also explains why the points, blunted, or even shaped into little craters, such as one sees with alternate-current arcs of 25 amperes and more, have, according to measurements made by me with the pyrophotometer or with lighthouse apparatus, sensibly the same brilliancy as that of the continuous current arc.

For an appreciable portion of each period the arc is quite extinguished, but for the rest of the time the passage of surface presents a more brilliant aspect than normally, because it is somewhat too small for the current.

Influence of the Nature of the Carbons.

On this point I dare least to announce any definite conclusions, on account of the complexity of the effects which may intervene. Assuming that volatilisation of carbon really does go on in the arc at a fixed temperature, the following conditions are still necessary to ensure that the nature of the carbon should have no influence:—

(i.) The carbons must only contain a very small proportion of foreign substances. Formerly this was not the case, but to-day it is nearly so in practice, thanks to the methods of purification employed by all carbon makers. The majority of electric-light carbons do not contain more than 4 per cent. of foreign matter, 2 per cent. being mineral salts. Here, for instance, are some analyses made by M. Le Chatelier at his laboratory in the École des Mines:—

Table II.

—	1.	2.	3.
Carbon	93·0	95·1	95·5
Oxygen, Nitrogen	4·5	1·68	1·8
Hydrogen	0·5	0·22	0·3
Ash	2·0	3·0	2·4

The oxygen and the hydrogen are almost entirely in the form of hygrometric water. Moreover, many of these bodies, as M. Violle rightly remarked, are eliminated before the carbon comes to boiling point.

(ii.) The *molecular state* of the light-emitting body must always be the same. Now, at the temperature of boiling carbon, carbon only exists as graphite. The thin incandescent layer must, therefore, of necessity always have the same molecular constitution, in contradistinction to that which takes place in the case of incandescent lamp filaments, the temperature of which is much lower. I have verified the graphite theory by scraping the surface of the crater after the carbon has cooled, it was found that it was transformed into graphite to a small depth. From this direction it would seem, therefore, as if there existed no cause of variation.

The carbon at the surface of the crater being almost pure and almost black graphite, the emissivity at the same temperature should be the same for all carbons, according to Kirchoff's law. As a matter of fact, experiments have not rigorously verified this constancy. Differences have been detected between the different

* See my recent Paper on "Lighthouse Electric Lights," read before the International Maritime Congress, in London, July, 1893. See also abstract in *The Electrician*, Vol. XXXI., September 1st, p. 479.

Digitized by Google

homogeneous carbons tested ;* soft carbons, in particular, appear to be less brilliant than hard carbons, as is shown by the results set forth in Table III.

Table III.

Total distance between the two screens 8,040 mm. surfaces :—Right hand screen 0·9038 sq. mm. Left hand screen 0·8135 sq. mm. Carbon employed in the right hand arc type L, with core ; average voltage.

Carbon used in the left-hand arc.	Distance of the Photometer in mm.		
	From left-hand arc.		From right-hand arc mean.
	Reading.	Mean.	
L (soft)...............	3,964 3,937 3,942 3,933 3,922	3,933	4,100
L (hard	3,853 3,820 3,907 3,852 3,878 3,840	3,858	4,182

Special carbons made out of shining retort graphite appeared to to be somewhat more brilliant than ordinary carbons. But tests were rendered very difficult by the continual displacement of the arc, which takes place with certain kinds of carbon, and the tests do not on that account merit absolute confidence. In all cases the differences detected were small compared to the differences which existed between the various carbons employed. These, according to the tests of M. le Chatelier, were comprised under two groups, A and B, which presented decidedly different molecular states, as will be seen by the following table :—

Type.	True specific gravity.	Calorific power.
A (soft)	1·60	7·94
B (hard)	2·00	7·76

We are, therefore, authorised to consider the brilliancy as independent of the specific gravity, and to set down the differences observed, above all to differences in the proportions of mineral salts present in the carbons.† These salts, usually rather refractory, only volatilise close to the crater, and may, therefore, play a part analagous to the core, about which I now propose to speak. If this explanation were not sufficient, it would be necessary to assume that a portion of the carbon of the arc escapes volatilisation, as in the case of the hissing arc.

(To be continued.)

* In Europe carbons are almost exclusively made out of graphite obtained from gas retort carbons ; this is sifted and mixed with different proportions of lamp-black, and agglomerated by means of oil tar. In America petroleum coke is also employed ; it contains much impurity, and results in inferior carbons.

† Perhaps also to a difference in emissive power.

LEGAL INTELLIGENCE.

The Medical Battery Company (Limited).

At Marlborough-street Police-court on Tuesday, C. B. Harness, managing director of the Medical Battery Company (Limited), J. M. M'Cully, C. B. Hollier, and Dudley Towers again surrendered to their bail before Mr. Hannay to answer the charges of having conspired together to defraud, and of having obtained by false pretences various sums of money.

Mr. FREDERICK THEOBALD BURBAGE, a provision dealer, of Liphook, Hants, was recalled and cross-examined by Mr. Gill.

Col. JEREMIAH BRASYER said he was a retired colonel of Her Majesty's Army, and lived at Margate. He was a C.B., and had served for thirty years in India and throughout the Mutiny. He was the prosecutor in the present case. About the middle of last year he was suffering from weakness in the loins. He saw many advertisements, and in consequence of reading them went to 52, Oxford-street. He could not fix the date of his first visit, but believed it was in June, 1892. When he went into the place he asked for Mr. Harness. Whoever the man that saw him was, he said, "We are Mr. Harness." Then he plainly and bluntly asked him about his means, saying, "What are your finances?" The Witness was vexed, and said he had not gone there to beg and could pay for what he required. Nothing was then said about his complaint. The man handed him a book (there were several persons standing about) and said, "Will you or can you sign that?" The book contained cheques. They filled up one and he signed it. After it had been signed the man said, "We will make a better man of you in a few days." A lad was then directed to take him upstairs. He went upstairs and got to a large saloon, where he was asked to sit down. He sat there until Dr. M'Cully came in and led him away to another room. M'Cully took him into his room and asked him to get on a chair which was on a raised platform. M'Cully then begun all sorts of antics, such as he had seen performed by fakirs in India. After he had sat down in the chair M'Cully walked round him swinging something. In the meantime a wheel was going round behind his back. That was all that took place on the first occasion. He went there three other times, when the same thing happened. On one occasion M'Cully put something stronger on, and he felt a pain at his shoulder which he could not bear. He called out to have it stopped as he could not bear it. Once another person operated upon him in place of M'Cully, and treated him in a gentler manner than M'Cully. After feeling the pain so badly he went home and felt that he had lost the use of his arm. He had not yet completely recovered. He had had nothing of the sort before he felt the pain. He got a belt at the establishment. He could not say where it was. He gave it to his solicitors. He could not say how long he wore it, but the discs caused blisters on his body. The blisters came out almost immediately, or, at any rate, after the second or third day. M'Cully told him there would be no extra charges. He received the letter produced, apparently signed by M'Cully, which enclosed an account for attendance at the Cannon-street Hotel, including cab fares, &c., amounting to £47. 15s. He remembered the cheque produced being drawn. He received no benefit from the treatment he received.

Cross-examined by Mr. AVORY : He was not treated at Oxford-street 17 times. He might have been there six times, but he could not be sure of anything on account of the confusion of mind they put him into.

Mr. AVORY : What did you give the cheque for 50 guineas for?—Because I suppose they asked me for it.

Continuing, the WITNESS said that he represented to Mr. Colyer what he had suffered, and left everything to him. For any information with reference to the action, he referred Mr. Avory to his solicitor and lawyer. When he went to Oxford-street he was suffering from an ache in his back. He went there to get relief, but only his pockets were relieved. He went to the place in the first instance to purchase a belt. At Folkestone, in June, 1892, he had no idea of getting married. He declined to say whether or not he contemplated marriage since that date.

Mr. HANNAY remanded the case at this stage until noon on Wednesday.

WEDNESDAY, DECEMBER 6TH.

On the hearing of the case being resumed on Wednesday, Col. BRASYER was recalled and cross-examined by Mr. A. R. Cluer on behalf of M'Cully. He said he went to the institution in Oxford-street to get a remedy for the pain he had in his back. He had read the advertisements concerning the place. M'Cully did not point out to him that treatment at his age was not likely to do him much good. He followed the advertisements, and seeing that so many had benefited by the treatment, according to the statements made in them, he thought that perhaps he would benefit by visiting Oxford-street. He could not remember how many times he visited the premises in Oxford-street. If it appeared in the books of the Company that he had been there 15 or 17 times he would not believe them. He did not believe in anything connected with the place. He could not tell the moment, but he had not been going there very long before he could tell that the treatment was doing him more harm than good. The people at the place said they would make a better man of him and set themselves above the Creator. He remembered telegraphing or sending a message from Cannon-street for Dr. M'Cully to go and see him. In answer to the message, M'Cully did go and see him. He might have told M'Cully that he was suffering from hernia. M'Cully did, upon that or another occasion, advise him to call in Mr. Stanley Boyd, of Harley-street, surgeon to the Charing Cross Hospital. Mr. Stanley Boyd attended him once at the Cannon-street Hotel, but whether more than once he could not say. Mr. Stanley Boyd and M'Cully agreed that he was ruptured, and afterwards M'Cully took him to Matthews, of New Oxford-street, and it might have been for the purpose of getting the description of truss which Mr. Stanley Boyd recommended.

Mr. PETER KEDDIE, an East India merchant, of The Terrace, Kennington-park, who gave evidence last week, was recalled and cross-examined by Mr. Gill. He said that he did not know who got the first belt for him. His mind was quite a blank as to how he got it. He wore the first belt about 2½ years, but not next to his skin. He pretty well used it up by wearing it. It was before he had the first belt that he was so ill that he had to go about on his hands and knees. While he was wearing the first belt he did not speak of the benefit it was doing him. His family knew of the benefit it was doing. He went and got a second one, but it was not because he thought the first one had done him good. He did not ask the people at Oxford-street about the cheque he signed for £105, because he was above doing such a thing. He went to his bank the day after he had given the cheque. He could not assign any reason why he did not ask his bankers to show him the cheque, but he felt he had been taken in and done for. He could not tell when the cheque came back to him, but he believed it did so in due course. He did not remember getting a receipt for the cheque from the people at Oxford-street. He would not swear that he had not been at Oxford-street 27 times, but he believed he had only visited the place 12 times. The only thing he had to complain of was the treatment when his back got ulcerated. He was told by the people at the institute to rest himself till it got well. When he saw the editor of the *Hawk* he was wearing the belt and said nothing to him about it. He was wearing one of the belts at the present moment. The receipt for the money he paid was not taken out of a book in his presence. Looking at the counterfoil produced, he saw that it bore his initials, and he had not the slightest doubt he had written them.

Digitized by Google

He had no recollection of what took place after he had been told that he would have paralysis.

The cross-examination of Col. BRASYER by Mr. A. R. CLUER was here resumed: He did not know what M'Cully paid for a certain liniment—it might have been 6d. or £50. He did not remember M'Cully coming often to the Cannon-street Hotel and rubbing his shoulders with the liniment. It was agreed three guineas should be paid in any event, but that if the hernia were reduced £10. 10s. should be paid. It had not been reduced. M'Cully came to see him at Margate, with a Mr. Herbert. They bullied him for money, and behaved in a rude way. He sent down £10 to M'Cully by his servant in consequence of the blustering way he was behaving. The treatment he had received at his hands had injured his arm, which was now somewhat better.

Mr. HANNAY adjourned the further hearing of the case till next Wednesday, allowing the same bail as before.

The first meeting of the creditors in the matter of the winding up of the Medical Battery Company (Limited) is to be held at the Holborn Restaurant, Holborn, W.C., to-day (Friday) at 11 a.m.

Chelsea Electricity Supply Company (Limited) v. London Electric Supply Corporation (Limited).

This was an action in the Court of Appeal on Wednesday, in which the defendants appealed against a decision of Mr. Justice Wright, in August last, by which an injunction was granted restraining them from laying any distributing mains for the supply of the electric light within the area described in Schedule A of the Chelsea Electric Lighting Order, 1886, except as provided by an agreement between the parties, dated July 9, 1889. On the case being called, it was explained that the parties had come to an agreement, and the Court made an order on the terms so arranged.

Manville v. Gramshaw.

This was an action before Mr. Justice Lawrence and a jury in the Queen's Bench Division last week, brought by Mr. E. Manville, consulting electrical engineer, against Dr. F. Sidney Gramshaw, of The Villas, Tillingdon, Easingwold, Yorkshire. The claim was to recover the balance of £200, due as premium for taking the defendant's son as pupil. The defendant pleaded that his son was learning nothing, and therefore he took him away.

In opening the case, Mr. WALTER said the plaintiff was electrical engineer to the Corporations of Dublin, Salford, Portsmouth, Kilkenny, and various London vestries, and in 1889, in connection with the Electrical Engineering Corporation, was carrying out an electrical installation at a mansion in Yorkshire, and Dr. Gramshaw negotiated then for his son to be a pupil of the Corporation. By plaintiff's influence, the premium was reduced from 300gs. to £200, and young Gramshaw went to the Corporation's works at West Drayton. On January 6, 1891, a fire occurred at the plaintiff's works, which destroyed much property, and placed the Corporation in considerable difficulties. When the Company went into liquidation, the defendant's son was transferred as a pupil from the Company to the plaintiff, and the latter sent him over to Dublin, where a large central station was being erected. After being there some time young Gramshaw left, and took a situation at a small salary. Evidence was given by electricians that young Gramshaw would have gained valuable experience if he had stayed with plaintiff in Dublin.

For the defence, Dr. GRAMSHAW and his son gave evidence. The former said he never agreed to transfer his son as pupil from the Company to the plaintiff, and the latter's testimony was to the effect that the working of the apparatus was not properly explained to him, and he left because he learned nothing.

After hearing the evidence and the Judge's summing up, the jury found a verdict for the plaintiff for the full amount claimed.

Fry v. St. James's and Pall Mall Electric Supply Company (Limited).

This was an appeal, heard yesterday by Lords Justices Lindley, A. L. Smith, and Davey, from a judgment of Mr. Justice Kekewich, who had decided that the plaintiff, a holder of Founders' shares in the defendant Company, was entitled to one-half of two sums of £1,000 which had been set aside by the Directors, before payment of dividend, as a reserve or capital redemption fund. The Company carried on its operations under a Provisional Order, and was liable to be bought up by the Local Authority after a period of 42 years, and it was to provide against the gradual depreciation of the property that the Directors, with the entire concurrence of the Ordinary shareholders, set aside £1,000 annually, this having now been done for two years. The Company contended that the holders of Founders' shares were bound, to the same extent as were the Ordinary shareholders, to accept the statement of accounts of the Directors and the certificate of the auditor. There was no impeachment of the *bonâ fides* of the Directors; but the plaintiff did try to go behind their statement and suggest that the accounts had not been properly dealt with in conformity with the Articles of Association. There was a stipulation in the Articles of Association that the Founders' shares should carry half the net profits after a dividend of 7 per cent. had been paid upon the Ordinary shares, and the plaintiff relied upon a clause in the Articles which provided that only such profits as would otherwise be available for dividend on the Ordinary shares should be set aside as a reserve fund.

Their LORDSHIPS held that the judge below was right in the construction he had placed upon the clause in the Articles of Association, and that there was intended to be a distinction between the Founders' shares and the Ordinary shares when the question of reserve came into consideration.

The appeal was therefore dismissed.

Urch v. Greenhill.

This was an action in the Lord Mayors' Court, London, by Mr. F. Urch against Mr. M. Greenhill, electrical engineer, of Mansion House-chambers, E.C., to recover £23, balance of principal alleged to be due upon two bills of exchange for £25 and £14 respectively, and costs of a judgment paid by the plaintiff in respect of the said bills. The bills were drawn by the defendant and accepted by the plaintiff, and were discounted by a Mr. Talbot, who subsequently sued the plaintiff, and defendant on the bills and obtained a joint judgment against them which had been satisfied by the plaintiff. The plaintiff now sought to recover from the drawer his contribution of the total expense. The defendant declined to pay, firstly, because there had been no notice of dishonour, and, secondly, because the bills were drawn for the accommodation of the acceptor, who received the whole of the money less the charges for discounting.

The jury found for the plaintiff, for whom judgment was entered, subject to a reference of the figures to the Registrar.

CORRESPONDENCE.

SOME NEW EFFECTS WITH VACUUM TUBES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Some months ago you were good enough to insert a short communication from me on some new effects produced by means of vacuum tubes. After further pursuing this matter I have a few more words to say on the subject. My experiments are still very incomplete, and the nature of the subject is such that a long time must elapse to cover even a small portion of this field of investigation. The object I have in view in publishing a few notes from time to time on the subject is partly to prevent anticipation by others, and partly to assist those who are engaged on similar work.

There have been a large number of theories advanced to explain the "dissociation" observed in vacuum tubes. I have come to the conclusion that the whole phenomenon is simply a question of interference, and is comparable to, if not actually identical with, "Newton's rings." I am not aware that anyone else has advanced this theory, although I have been looking up the subject of late. I have had some special tubes made for illustrating this theory, which I hope to show in public later on. Tesla's experiments go a long way to confirm my view. His experiment of connecting two bars of metal to a high-frequency source of current, and then placing a lamp across these bars, is well known. If the connections of these lamps to the bars are shifted up and down, then the lamp at some places will glow, and at others remain unaffected, indicating nodal points. The behaviour of powders of various substances mixed together, under the action of an alternate current, also tends to show this circumstance. The great advantage, however, of working with vacuum tubes is that it is possible to actually see what is going on. I think that a great deal of future investigation will be accomplished by this method.—Yours, &c., DAVID SALOMONS.

Broomhill, Tunbridge Wells, Dec. 6, 1893.

AN ELECTROLYTIC "RIDDLE."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With respect to the "riddle" propounded on page 108 of your last issue, I would point out that the experiment was in effect made in the year 1880 (*Phil. Mag.*, November, 1880), when the late Dr. Guthrie and I made comparative measures of the conductivities of liquids, in which the currents were induced by a moving magnetic field, there being no electrodes. Of course there is no evolution of gas, and no effective decomposition.—Yours, &c., C. V. BOYS.

THE LATE A. RECKENZAUN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you allow me a space in the columns of your journal—which has amongst its readers so many of my late husband's friends—to thank them for sending me, in such numbers, letters of sympathy and condolence.

Their number is far too great for me to reply to them individually, and I hope you will give me this opportunity of expressing to them my warmest thanks, and the gratification it is to me to know how universally my husband was beloved and respected.—Yours, &c., E. RECKENZAUN.

Digitized by Google

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

The 1893 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES DIRECTORY AND HANDBOOK" contains over 1,000 pages, several new and handy features having been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

The 1894 Edition is in preparation, and will be published in January next. New names, alterations of addresses, &c., should be sent in at once. The Directory blanks and circulars are not sent out until late in the year, in order that the most recent, and consequently the *correct*, addresses *only* shall appear in the book. Full printed particulars can be obtained, post free, from "The Publisher," *Electrician* Office.

TENDERS INVITED.—The Swindon New Town Local Board invite tenders for the supply of gas, oil, or electric light for the public lighting, for one year, commencing January 1st next. Tenders must be sent in by the 11th inst.

——— The Derby Corporation invite tenders for the wiring, fittings, &c., for the various public buildings in their electric-lighting area. Tenders must be in by noon of the 16th inst.

——— The Walton-le-Dale Local Board invite tenders under various contracts for work in connection with their sewerage and sewage disposal works. Contract No. 5 (Sections A and B) is for steam engines, pumps, boilers, and fittings. Particulars can be obtained of Mr. J. S. Spencer, Haworth-buildings, Manchester, and tenders must be sent in by noon on Saturday, the 16th inst.

TENDERS ACCEPTED.—The Electric Lighting Committee of the Taunton Town Council have received a number of tenders for plant and apparatus required in the extension of the electric-lighting installation, and the following have been accepted:—Messrs. Laing, Wharton and Down, for small alternator and exciter, £284; for two 30-kilowatt transformers and switches, £261. 16s. Messrs. Easted and Chandler, for 50-H.P. high-speed engine, £243. British Insulated Wire Company (Limited), for armoured concentric cable (quarter mile), £81. 5s. Fowler-Waring Cables Company (Limited), for one mile of triple concentric cable, at 7s. 4½d. per yard. The last tender is accepted under certain conditions as to jointing, completing the work, making good and guaranteeing cable. The tender for the two 30-kilowatt transformers and switches was accepted on condition that Mr. Newton, of Taunton, could not satisfy Dr. Fleming on the subject of his tender for this apparatus. If Mr. Newton's tender proves satisfactory, then his tender was to be accepted in place of that of Messrs. Laing, Wharton and Down.

APPOINTMENTS VACANT.—The City of Londonderry require a chief engineer for the Londonderry electric lighting station; also an engine man and assistant, and a dynamo tender. Further particulars are given in our advertisement columns, and applications must be sent in not later than Tuesday, December 12th, to the Chairman of the Lighting Committee, Guildhall, Londonderry, Ireland.

LIQUIDATIONS.—Mr. Theophilus Coad has presented a petition for winding up the Aladdin Primary Electric Battery Company (Limited). The petition will be heard at the Courts of Justice, Strand, London, W.C., on the 19th inst. Mr. J. R. Pakeman, 20, Bucklersbury, is solicitor.

——— The following companies are to be voluntarily wound up:—The Corifact Syndicate (Limited); claims to be sent in to Mr. E. Hill, 69, Mark-lane, E.C., by the 22nd inst. Electrical Wonder Company (Limited); resolution passed November 27th; Mr. Howard Felgate, 115, Strand, W.C., liquidator. Fowler Insulator Syndicate (Limited), 5, Lime-street, E.C; Mr. R. R. Fastnedge, liquidator. J. R. Powditch and Co. (Limited); Mr. Edwin Hayes, 107, Cannon-street, E.C., liquidator.

BANKRUPTCY.—At Nottingham William Andrews, electrician, of 6, St. Ann's-valley, and 118, Hungerhill-road, Nottingham, was examined last week. The Official Receiver stated that the debtor had furnished certain information, but it was very far from accounting for the £900 which, at his examination, he admitted having received within a period of two years. The debtor had, however, kept no books, and as there seemed no probability of extracting any account more definite from him, there was no utility in keeping open the examination. Debtor was accordingly allowed to pass.

APPLICATION FOR DISCHARGE.—An application for discharge by Walter Rowbotham, electrical engineer, of Tintern Load, Moss Side, near Manchester, is to be heard at Salford County Court at 10 o'clock on January 9th.

ALLEGED FRAUD.—Henry Everard Hunt, electrical engineer, Manager of the Taunton Electric Light Works, has been remanded at the Taunton Police Court, charged with forging a promissory note for £233 with intent to defraud.

LIGHTNING CONDUCTORS.—Messrs. Morris and Gold send us some illustrated particulars of their system of lightning protection for church spires, chimney shafts, &c. The illustrations include several recent contracts.

MESSRS. GILBERT AND CO.—This firm inform us that they have opened a small central station at Cardiff for supplying current to the Philharmonic Restaurant, and other places close at hand. The plant at Messrs. Gilbert's installation of Messrs. Derry and Sons' premises, at Kensington, London, has recently been added to, and now more than 100 arc lamps have been provided, the majority of which are already working. Owing to increase of business the firm have had to extend their Hanway-street premises.

EXHIBITION.—The Mayors of the principal boroughs have received a circular stating that a committee of about 50 gentlemen, 25 of whom are members of Parliament, has been formed to promote a scheme for holding during 1896 or 1897, in London, a colossal International Exhibition.

PRICE OF GAS NORTH OF THE THAMES.—The St. Luke's Vestry is taking up the question of the difference of the price in gas north and south of the Thames. In the south the average price is 2s. 6d. per thousand, and in the north 3s. 1d.; and it is felt that some explanation is necessary why this difference should exist. The Gas Company pleads that more wages are paid, and that coal costs more, but the St. Luke's Vestry consider that the 12¼ per cent. received by the shareholders of the Gas Light and Coke Company chiefly accounts for the difference. The Islington Vestry have decided to support the action of St. Luke's in this matter, and no doubt other local authorities will follow. It is remarkable that an attempt has not previously been made by the local authorities to rectify this anomaly.

WOLFRAMINIUM.—Messrs. Van Wart, Leighton and Co. have on show at the National Cycle Show, now being held at the Crystal Palace, a new alloy of Roman metal, to which they have given the name of "Wolframinium." Cycle parts and also a complete cycle made in the metal are on show.

"THE ENGINEERING MAGAZINE."—The contents of the December number of this magazine are as varied and interesting as usual, and include "An English View of the World's Fair," by J. Stephen Jeans; "The Iron-Ore Region of Lake Superior," by Richard A. Parker; "History of Strikes in America," by Arthur A. Freeman; "Electric Power at the World's Fair," by Nelson W. Perry; "Relation of Chemistry to Engineering," by Joseph Torrey; "American and other Patent Systems," by Casper L. Redfield; and the usual Editorial Departments on Electricity, Architecture, Railways, Mining, and Metallurgy, and Machine-Shop Practice. The next number of the magazine is to be a souvenir edition, "The World's Fair in Retrospect," with over a hundred superb engravings, forming, with the specially-written letterpress, a splendid memorial of the great Chicago Exhibition. Orders for the European edition of this number should, in order to prevent disappointment, be sent in as early as possible to the publisher, Mr. George Tucker, Salisbury-court, Fleet-street, E.C.

THE HOOKHAM METER.—Messrs. Chamberlain and Hookham (Limited), of Birmingham, forward us a neatly-printed and illustrated descriptive pamphlet of the Hookham meter, including, amongst other particulars, the report on the meter by Mr. James Swinburne, and a reprint from the *Phil. Mag.* of the Paper by Mr. George Hookham, M.A., on "Permanent Magnetic Circuits." Instructions for using the meter, and prices, form part of the pamphlet.

THE "O.E." METER.—Mr. Joseph Edmondson sends us a useful hanging mounted sheet containing particulars of the "O.E." meter, and including a number of useful tables.

ELECTRICAL ADVERTISING SIGNS.—The Partington Advertising Company have entered into an agreement with the Electrical Advertising Syndicate (Limited), taking the sole agency in London for the sale of electrical letters (René Upward's patents).

SMITHFIELD CLUB SHOW.—This annual show has been held during the current week at the Agricultural Hall, London, N., and for the first time at these gatherings the electric light was in evidence. Messrs. Vaughan and Brown have installed a number of Luna arc lamps, and the light appears to have given satisfaction. Amongst the exhibitors were Messrs. Robey and Co., of Lincoln, who had on show a number of their well-known engines, several of which are specially designed for electric lighting work. Included in the exhibits was a high-speed vertical engine, for use in mills, factories, &c., where space is limited. All the wearing parts of this machine have large surfaces and are provided with means for self-lubrication. A Robey patent horizontal oil engine was a feature of the exhibit: the engine works on the Otto cycle, and contains a chamber capable of holding a week's supply of petroleum for working. All parts are easily accessible, and the

Digitized by Google

combustion is perfect. The oil used in these engines can be the ordinary unrefined heavy petroleum of the cheapest kind. Messrs. Ransomes, Sims and Jeffries, of Ipswich, had as usual a fine display, including several of the latest patterns of both vertical and horizontal engines, and their new 6 and 8 H.P. portable engines, which have large steam-jacketed cylinders, wrought-iron crank shaft brackets, raised top fire boxes, and piston valve governors. The F vertical engine is connected with a new patent multitubular vertical boiler, so arranged as to present a maximum amount of heating surface in the smallest possible space, and giving ready access to every part of the boiler for cleaning, &c. Messrs. Marshall, Sons and Co. also had an excellent exhibit, including a 7 H.P. portable engine of the latest design, and a 10 H.P. compound engine, of which a large number are included in electric lighting plants throughout the country. A new 10in. fixed high-speed engine was also on show, fitted with the latest improvements in sight-feed lubricators, crank-shaft governors, &c. An engine specially designed for electric lighting purposes was a 6½in. vertical engine, fitted with Moore's crank-shaft governors. Messrs. Marshall and Sons have recently introduced a new 10in. engine fitted with Proell gear, sight-feed lubricators, Corins's exhaust pipes, chain gear, and all the latest improvements. This engine attracted considerable attention. Mr. E. S. Hindley, of Bourton, Dorset, had on show a number of small-power vertical engines for which the firm are well known, in addition to a 10 H.P. horizontal steam engine with disc crank and a 12 H.P. high-speed engine, of which a number have been supplied for electric lighting installations. These high-speed engines have been designed to work with steam up to 120lb. pressure, special provision being made for continuous lubrication and to prevent waste of oil. The governor is of special design, ensuring perfect regularity under sudden variations of work. Messrs. W. H. Willcox and Co. have their usual excellent exhibit of general engineers' stores in great variety. This is one of the handsomest stalls in the Smithfield Show, and it is doubtful whether any firm in the trade could make a more representative display of general stores. The Britannia Company exhibit Root's patent oil engines, of which a three-horse example was at work. Other exhibitors included Messrs R. Hornsby and Sons, the Campbell Gas Engine Company, and Messrs. John Fowler and Co. of Leeds.

Aberdeen.—The Gas Committee of the Aberdeen Town Council last week paid a visit to the new electric lighting station in Cotton-street. Mr. Murray, the city's electrical engineer, explained the various machinery and apparatus to the members of the Committee, and, in the course of a discussion which followed the visit, Mr. Johnston stated that it was unquestionably the best business the Corporation had undertaken for some time. That body had been handicapped seriously by having had to buy up the Gas Works from a company, and he believed that if they had not gone in for the electric light for themselves a company would have taken the matter up, which would ultimately have resulted in the Corporation having to buy them out. They might suffer a little loss at the start, but if they did as well as other towns were doing it would soon be a paying concern. He had no doubt whatever that as soon as the station was in condition to supply the light it would be very readily taken up by the townspeople generally. He was sorry to find that it was not anticipated the light would be ready before the middle of January, which was a disappointment to some of them, who would have liked to have seen the light in use at the beginning of the new year. Treasurer Bissett, at whose initiation the electric light work was undertaken, expressed the satisfaction he felt at the general success so far, and referred to the fact that it was only by the casting vote of the Chairman that it was agreed the Corporation should take the matter up. The Committee ultimately unanimously sanctioned the purchase of a quantity of necessary material, amounting in all to about £520.——Messrs. Drake and Gorham have recently completed an electric-lighting installation at Ardoe House, Aberdeen, for which water-power is obtained from the Burn of Ardoe. The plant includes a turbine supplied by Messrs. Gilbert Gilkes and Co., of Kendal, which is placed over a brick well 20ft. deep, from which the waste water is conducted, supplying a head of water of 63 feet.

Assessment of Electric Lighting Plant in the City of London.—At the meeting of the City Guardians on Tuesday, Mr. Klenck called attention to the electric lighting companies within the City area, with a view of having their plant, &c., assessed in the same way as other City undertakings and properties. Mr. Odell, Chairman of the Assessment Committee, stated that the matter was at present receiving the attention of the committee.

Bandon.—A recent meeting of the Town Commissioners discussed the question of opposing the application made by the Bandon Electric Lighting Company for a Provisional Order. After some discussion it was decided that the Board should oppose the scheme.

Blackburn.—Major-General Crozier held a Local Government inquiry last week on the application by the Corporation for powers for borrowing £200,000 for the purpose of the erection of new gasworks. The old gasworks will probably be devoted to electric-lighting purposes

Bray.—The liquidator of the estate of Messrs. J. E. H. Gordon and Co. has written to the Bray Township Commissioners, offering to dispose of his client's interest in the Bray Electricity Works to the Commissioners.

Bristol.—It is anticipated that the Electrical Committee of the Corporation will require to borrow about £20,000 for further extension of the electric lighting plant. The number of applications for the light have exceeded expectations, and an expenditure of £4,000 for additional plant is immediately necessary.

Burnley.—It has been decided to supply the electric light at Burnley at 4d. per unit. Applications for light equal to 3,434 lamps of 8-c.p. have been received.

Camberwell.—A meeting of the Vestry was held on Wednesday for sending a memorial to the Board of Trade for a Provisional Order under the Electric Lighting Acts. The standing orders of the Board of Trade require a statement as to the amount of capital proposed to be expended in the undertaking, and the Vestry, on the estimates of an expert, have quoted £50,000.

Castleford.—At the annual meeting of the Castleford Tradesmen's Association Mr. Little was elected President for the ensuing year, and, in the course of some remarks, suggested that instead of the Local Board disposing of the surplus plant at the disused waterworks it should be utilised for electric lighting purposes. The Board has already had expert evidence on the subject, and it appears likely that before next winter the town will be provided with the electric light.

Cathedral Lighting.—The Restoration Committee of St. Paul's Cathedral have discussed the question of installing the electric light in the cathedral, and have appointed a sub-committee to inquire what the expense would be. If it is ultimately decided to have the light, an appeal will be made for special funds.

Chelmsford.—The local authorities of Chelmsford are again discussing the question of the electric light, and at last week's meeting of the Town Council the Lighting Committee presented a report recommending the renewal of the contract for the public lighting of the town by electricity on the same terms as before; also the approval of the Provisional Order for which Messrs. Crompton and Company are applying to the Board of Trade; and further, the modification of an order by the Board of Trade that the electric-light wires in some of the principal streets should be placed underground. Messrs. Crompton's proposed Provisional Order was opposed by Aldermen Chancellor and Duffield, who complained that under its provisions Messrs. Crompton would obtain the whole of the private lighting for 42 years; but it was explained that the Provisional Order does not touch the question of public lighting, and there is nothing to prevent the Town Council from putting down its own plant for illuminating the streets. The matter is under discussion in committee of the whole Council.

Dover.—The Dover Electric Light Supply Company having been formed, and the official transfer of the powers under the Provisional Order from the Corporation to the Company having been legally executed, the Directors of the Brush Company called together last week a number of the principal townsmen, under the chairmanship of Sir W. H. Crundall, J.P., who is Mayor of Dover, and Chairman of the new company. The Chairman briefly referred to the somewhat lengthy negotiations which preceded the formation of the Company, and Mr. Sellon gave an interesting account of the prospects of electric lighting in the town. It was stated that arc lights of 3,000 c.p. are to be used for the public lighting.

Dudley.—Alderman Bagott (not Bigot), in moving the adoption of the Streets and Gas Committee's report, submitted a statement showing the number of towns that had obtained Orders for electric lighting, and pointed out that the Council, if they proceeded with the suggested scheme, after obtaining the Order, would have to get an electrical engineer at a salary of £400 or £500 per annum, then spend £20,000 or £30,000, and take all the risk. He further stated that out of 60 towns which had applied for Orders, only *four* had gone on with their schemes. He suggested that Dudley should join those local bodies who were watching to see if success attended those who had decided to proceed with the work.

Eccles.—The Tramways and Electric Lighting Committee of the Town Council will, at their next meeting, discuss the advisability of taking steps to light certain portions of the Borough with the electric light. The ratepayers will be consulted on the subject, we understand, shortly.

Edinburgh.—A considerable extension of the electric lighting area is under consideration by the Lord Provost's Committee.——A letter was received on Tuesday last by the Town Council from Messrs. Dick, Kerr and Co., asking to be allowed to sub-lease the

Digitized by Google

Edinburgh tramway undertaking to the Edinburgh Tramway Company (Limited). After some discussion, a proposal that Messrs. Dick, Kerr and Co.'s letter remain on the table for one month was adopted.

FLEETWOOD.—The Electric Lighting Committee are still considering the tenders received for carrying out the electric-lighting scheme, and have adjourned the further consideration of the matter for a few days.

THE GENERAL POST OFFICE.—The new seven-storied building just completing for the use of the postal and telegraph authorities is being wired throughout for the electric light. The new building is one of the largest in London, and is known as the G.P.O. "North," to distinguish it from the older buildings known as "West" and "East." Nearly 200 H.P. will be necessary to supply current for about 2,000 16-c.p. lamps, which will ultimately be installed. The wiring work is being carried out by the department's own staff. A large increase in the generating machinery will be necessary, although it is intended to take a portion of the current from the "East" building. The machinery in this building, however, appears to already have its capacity severely taxed at times.

HACKNEY.—A special committee, appointed by the Board of Works, to consider the subject of electric lighting has sent in its report, and the matter is now under consideration. Under the powers recently obtained by the Board the parishes of Hackney and Stoke Newington are to be supplied with the electric light in due course.

HALIFAX.—An exhibition, interesting both to sanitarians and electricians, is now being held at Halifax for the purpose of demonstrating the feasibility of generating steam for electric lighting, &c., with ash-bin refuse as the only fuel. The installation (close to the Northern Engineering Company's premises in Parkinson-lane) consists of Livet's two-furnaced expanding flue steam generators, capable of giving off 300 H.P. when town's refuse is burnt. An electrical installation, consisting of a Parsons turbo-electric generator, is being put down, which will consist of a projector search-light of 25,000 c.p., and a full complement of arc lamps. These steam generators, instead of only destroying the refuse as "destructors" do, utilise it to the fullest advantage by turning it into steam.

HAMMERSMITH.—At the last meeting of the Hammersmith Vestry it was decided to instruct Messrs. Morgan Williams and King, of Westminster, to prepare a report for the carrying into effect the terms of the Provisional Order recently obtained, at a fee of 100gs.

HAMPSTEAD.—At the last meeting of the Hampstead Vestry a letter was received from the London County Council in reference to the application of the Vestry for a loan of £5,000, part of a sum of £25,000 for electric lighting purposes, and making inquiries as to the intention of the Vestry to make provision for a periodical replacement of machinery and plant by the establishment of a depreciation fund. The matter was referred to the Electric Lighting Committee, whose report on the subject of electric lighting generally is expected. The London County Council, on Tuesday, decided to lend the Vestry the sum of £25,000 for twenty-five years.

HULL.—Dr. Holder, the Chairman of the Electric Lighting Committee of the Hull Corporation, at the last meeting submitted a report from the Electric Construction Company (Limited), submitting their views upon the subject of electric traction. The Company stated their readiness to negotiate for the electrical equipment of a line of tramway, and for its subsequent working, at a figure much less than if worked by either horse, steam, or other mechanical power. After some discussion it was decided to refer the letter to the Tramways Sub-Committee, to be discussed by them in relation to the utilisation of heat from the destructors for the purposes of electric supply. Mr. G. F. Priestly has written to the Committee, calling attention to a new type of refuse destructor, with special reference to its being utilised in the town supply of electricity. Satisfaction was expressed by the Committee at the large number of customers already taking the light.

LANCASTER.—The price for electric current was fixed at 4½d. per unit at the last meeting of the Town Council. Amongst a quantity of plant and material authorised to be purchased were 50 Ferranti meters. An extension of the light is under consideration.

LEEDS.—The Highways Committee of the Leeds City Council recently discussed the subject of applying electricity to the Leeds tramways, which shortly come into the possession of the Corporation. Horse and steam power are at present used. A discussion took place upon various points raised in the consultation with Mr. R. Hammond, but no definite understanding was arrived at. The matter is to be further discussed.

LEIGH.—Amongst the buildings recently lighted, or which are being wired for the electric light, are the Athletic Clubs' Grounds and rooms and the Theatre Royal. A number of the principal shops are adopting the light, and Mr. W. Boydell, of Brown-street Ironworks, is working energetically to make it a success in the town.

LIVERPOOL.—The Church for the Blind in Hardman-street has been fitted with an electric organ by the Hope-Jones Electric Organ Company, of Birkenhead. The first trial of the organ proved highly satisfactory.

LLANDUDNO.—A public meeting was held last week to discuss the project of an electric railway up the Great Orme's Head, and a resolution approving of the proposal was carried by a large majority. The project, however, meets with considerable local opposition.

LYNTON.—At the last meeting of the Local Board the Clerk announced that the Electric Lighting Company were unable to supply more lights at present, as the entire capacity of their plant was already taken up.

MARGATE.—A Committee of the Town Council, specially appointed to consider electric lighting and tramway schemes, recommends that such schemes be not entertained, "as the time is too limited for a proper consideration of these matters." The committee's report has been adopted, so that nothing can be done in the matter until next year.

OMNIBUS LIGHTING.—The London General Omnibus Company were last week summoned for permitting a number of omnibuses to be in a public thoroughfare after sunset without a light. The Secretary of the Company explained that the vehicles were fitted with the electric light, which answered admirably in the summer, but were insufficiently supplied with battery power for winter lighting. He, however, was able to state that a new contract had been entered into by which all future liability of the kind would be obviated. After this explanation the magistrate imposed a nominal fine of 1s. and costs in each case.

OXFORD.—Messrs. Girdlestone, Tatham and Co. have been instructed to proceed with the work of installing the electric light at Oriel College. The work is to be carried out during the Christmas vacation.

PORT ELIZABETH (SOUTH AFRICA).—The Town Council of Port Elizabeth are anxiously discussing the question of lighting the port by electricity, and there seems every probability of an affirmative vote being obtained.

PORTHCAWL.—The local Electric Light Company have induced the Local Board to accept their offer for erecting and maintaining 23 electric lamps in the public streets.

RUSSIA.—It is reported that the Russian Minister of Finance has decided upon the issue of a decree exempting from Customs duties any foreign goods intended for Russian exhibitions.

ST. HELENS.—A sub-committee of the Town Council has been appointed to superintend the supply of electricity within the borough.

TAUNTON.—The Electric Lighting Committee of the Town Council have considered Dr. Fleming's proposal for the extension of the electric light. They will get rid of the small house transformers, and the town will in future be supplied from transformer sub-stations. Dr. Fleming considered it necessary to at once commence putting down underground mains, and work has been commenced in No. 1 district. Dr. Fleming has reported upon a number of tenders sent in to the Committee, and those accepted are detailed above.

TWICKENHAM.—The Local Board recently issued a circular asking support for their electric-lighting scheme. Of the circulars issued 133 were not returned, 134 returned in blank, 92 in favour of gas, and 274 in favour of electricity. The present annual cost of lighting houses where electricity is preferred is £3,006. 10s., and occupiers of these houses will be willing to pay £3,281. 14s. per annum for electricity, the number of lights required being 5,708. After some discussion it was decided to abandon the electric-lighting scheme for the present.

WALSALL.—The Town Council will have before them at their meeting on Monday next the proposal of the General Purposes Committee that the Council apply to the Board of Trade for their approval of the adoption of a scheme for electric lighting for the borough, and to the Local Government Board for sanction for a loan of £19,650, in addition to the estimated cost of the site for the works. It will be remembered that contracts have already been provisionally accepted from the Electric Construction Company (Limited), for £10,003; Messrs. Bumsted and Chandler, for £1,350; and Messrs. H. and T. Danks, for £805, for final acceptance as soon as the approval of the Board of Trade and the sanction of the Local Government Board is received.

WINCHESTER.—The Corporation have before them a scheme of electric lighting, which would, if carried out, involve an outlay of about £20,000, and would be adopted only for the more central parts of the city, leaving out the suburbs of St. Cross and other large ratepaying districts. It has been urged on the civic authorities that if there were a large participation in the scheme by private and public institutions, shops, &c., the cost would be greatly reduced, and to ascertain how many such will pledge themselves to

Digitized by Google

adopt the light, a professional electric expert is to be employed to canvass the city, explaining the cost of fitting, the mode of lighting and other details. The result will not be known till February.

WORCESTER.—A rumour was current last week that a serious misfortune had happened to the works at Powick. It appears, however, that a landslip had occurred owing to the continued rains, but that no damage was done to the works now in progress——. The Water and Sewage Committee have decided that the surveyor shall consult with Mr. C. Hawksley, the Corporation's engineer, with a view of deciding the extent to which electricity can be utilised for pumping or purifying the sewage in connection with the new schemes which the Corporation have now under consideration.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

October 31, 1891.

20,557. E. REDANTZ. Liverpool. Improvements in electrical switches

20,584. A. J. MARQUAND and E. HANCOCK. London. Improvements in the manufacture of elements for electric or secondary batteries.

November 1, 1893.

20,625. H. T. BARNETT. London. Improvements in and connected with carbon electrode connections.

20,686. W. E. GRAY and W. A. PRICE. London. Improvements in electrical condensers.

20,698. G. G. M. HARDINGHAM. London. Improvements in, and in connection with, electric cables. (The firm of Felten and Guilleaume, Germany.)*

20,715. W. E. F. RUCKERT. London. An electrical heating apparatus.*

November 2, 1893.

20,723. W. T. GOOLDEN and S. EVERSHED. London. Improvements in electric measuring instruments.

20,732. W. ALDRED. Sheffield. An electrical or mechanical apparatus in connection with a ship's sounding lead, or for cognate purposes.

20,735. J. BALL. Manchester. Improvements in lightning conductors.*

20,788. C. DENN, J. COCKER, and C. DENN. London. Improvements in electric stop motions for warping machines.

20,793. A. MUIRHEAD. London. Improvements in recording instruments for electric telegraphs.

20,799. M. H. HARTOGH. London. Improvements in electric incandescent lamps.*

20,816. H. R. KEITHLEY. London. Improvements in connectors for electric conductors.

November 3, 1893.

20,837. W. E. AYRTON and T. MATHER. London. Improvements in electrostatic and other electrical measuring instruments.

20,840. A. E. SCHURR. Leigh-on-Sea. Electric firedamp indicator. (J. Cauderay, Switzerland.)

20,847. W. H. SCOTT. Norwich. Improvements in carbon brushes, blocks, or collectors, for electric generators and motors.

20,859. F. G. TREHAME. Cardiff. A process by which, by combined chemical and electrical action, he obtains motive power.

20,883. BULLERS (LIMITED) and E. J. CHAMBERS. London. Improvements in brackets or supports for insulators for telegraphic, telephonic, and other like purposes.

20,891. P. A. NEWTON. London. Improvements in phonographs and telephones. (A. Nobel, France.)

20,896. SIEMENS BROS. and Co. (LIMITED). London. Apparatus for working semaphore signals by means of electric currents. (Messrs. Siemens and Halske, Germany.)

November 4, 1893.

20,915. W. E. AYRTON and T. MATHER. London. Improvements in alternate-current synchronisers.

20,923. H. T. BARNETT. London. Improvements in the means of charging and discharging primary electric batteries.

20,966. J. PLUMMER. Midlothian. Improved incandescent electric lamp.

20,975. J. A. S. GREGG. London. Improvements in voltaic batteries.

21,004. K. RODLER. London. A method of, and apparatus for, electrically protecting trains.

November 6, 1893.

21,046. A. M. THOMPSON and W. G. WEBB. Crewe. Improvements in electric switches.

21,077. C. E. H. EDMAN and J. GREEN. London. Improvements in electrical arc lamps.

November 7, 1893.

21,094. H. F. LAUGHTON. London. A method of improving electric light switches, bell pushes, keyhole plates, door numbers, name plates, dials of clocks, house fittings, and the like, by the application of luminous paints thereto.

21,117. R. W. WEEKES. Manchester. Improvements in and relating to electrical dynamometric governors.

21,140. G. COHEN. Manchester. Improvements in medical electrical appliances.

21,192. G. S. RAM. London. Improvements in incandescent electric lamps.

November 8, 1893.

21,199. W. L. SPENCE. Pollokshields, N.B. Power transmission by alternate-current motors.

21,201. F. T. TROUTON. Dublin. A multiple circuit microphonic transmitter.

21,270. J. A. MURDOCH. London. Improvements in and in constructing pianoforte cases for lighting music desks by electricity.

November 9, 1893.

21,324. S. Z. DE FERRANTI. Liverpool. Improved electric cables and method of, and apparatus for, manufacturing the same.*

21,327. E. BERGMANN and C. ERBEN. Liverpool. Improvements in electric meters.

November 10, 1893.

21,370. W. H. TURCAN, and R. C. MORTON. Glasgow. Improvements in mouthpieces for telephone transmitters.

21,379. A. G. ADAMSON. Glasgow. Improvements in the application of electric light for photographic purposes and apparatus therefor.

21,418. A. CROSS and H. SIMON. London. Automatic burglar-proof shutter for inside of jewellers' window with electrical alarm.

21,430. C. J. P. ROBERTSON. London. Improvements relating to incandescent electric lamps.*

21,434. F. W. SCHINDLER. London. Improvements in electrically heated ovens.

21,435. F. W. SCHINDLER. London. Contact-device or circuit-connection for electric heating bodies, and analogous electrical appliances.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d. each.

1892.

19,919. DE SOLOMÉ. Electric conductors.

20,445. RAAB. Electric meters.

22,261. HILLS. Electric arc lamps.

23,101A. SCHROEDER, C. A., J. H., and H. E. R. Galvanic batteries.

24,009. CROMPTON and CHAMBERS. Pipes for electric cables, &c.

1893.

17,564. KOCH. Electric accumulators.

18,323. LEIGH (Chevallier). Electric batteries.

18,480. RAHNER. Dynamo-electric machines, &c.

18,524. BURNS, J. R. and W. F. Indicators for telephone stations, &c.

COMPANIES' MEETINGS.

Elmore's French Patent Copper Depositing Company (Limited).

Mr. C. J. Stewart (the Official Receiver) presided on Tuesday last at the Holborn Restaurant, London, W.C., at a meeting of the English creditors in the above Company.

The CHAIRMAN expressed a wish that Mr. Duncan should be appointed liquidator, and this was agreed to. He proceeded to say that he had been asked by the Directors to mention that of their fees, which appeared in the statement of deficiency as £3,600 (see last week's *Electrician*), part was receivable in cash and part in Preference shares.

The meeting was subsequently adjourned until the 20th inst.

At the meeting of shareholders, held in the afternoon, also under the presidency of Mr. Stewart, the CHAIRMAN attributed the failure of the Company to the fact that the works were undertaken on too large a scale in proportion to the capital. It was intended to raise more capital when the merits of the process had been proved; but this had not been done by the time the additional capital was required, and, consequently, the Preference shares were not subscribed for to the extent which had been hoped. The price paid by the Company for the patents was £183,375, of which £116,000 was paid in cash. To that had been added a large expenditure on works, bringing up the total cost of the patents and works to £311,138. That, however, did not include the amount of £17,000 spent in addition, in improving and experimenting on these patents. One grave difficulty which he had had to face in unravelling the affairs of the Company was the fact that the whole of its affairs seemed to have been mixed up with the firm of Messrs. Woodhouse and Rawson United (Limited). There was one office, one secretary, and the whole of the correspondence of the two Companies appeared to have been placed together. In justice to the Directors he would like to say that of the fees paid to them—£3,000 in all—part was paid in cash and part in Preference shares, while the Directors had lent the Company upwards of £1,400. In justice also to Mr. F. L. Rawson (who he had mentioned in his statement of affairs had exercised great influence in the management of the Company) he would like to add that it was in the financial management of the Company when it got into difficulties. Mr. Rawson had obtained large sums of money for the Company at reasonable rates of interest, and was not responsible for the high rates mentioned in his report. Nor was Mr. Rawson responsible for the management of the Company and the spending of these large sums. Mr. Rawson had given him the opportunity of looking into these matters.

Digitized by Google

Mr. F. L. RAWSON stated that from the words of the Official Receiver it might be understood that the affairs of Woodhouse and Rawson and the Elmore Companies were mixed up, whereas the Official Receiver intended to convey that the affairs of the different Elmore Companies were mixed up. In order to save expense, all the Elmore Companies employed one secretary, and the correspondence was kept together, but all the necessary books were kept separate.

The OFFICIAL RECEIVER: Yes; Mr. Rawson is right, it is as he states.

Mr. RAWSON (continuing): He had sent a long letter to the Official Receiver, showing exactly his connection with the French Elmore Company, giving all the facts in such a way that the Official Receiver could check the statements made. In the early days of the Company he had assisted in connection with the patents, and from that day to this the Company had never had any difficulties with their patents. When M. Secretan insisted upon an expenditure of £80,000 upon the works if he took the post as manager, he attended a Board at which the English Elmore officials were present, who stated that the English Company would be turning out 20 tons per week in three months. He then told the French Elmore Board that if this were the case he could obtain any reasonable amount that the French Company required at a moderate rate of interest. Experience had since justified this statement. His next connection with the Company was in November, 1892, when the Board came to him and, as they were in financial difficulties, placed their money matters in his hands. Between that date and July, 1893, he obtained for them over £100,000, at an average rate of not more than 6 per cent. per annum. He then stated that if they could turn out 20 tons per week for twelve consecutive weeks he would obtain for them £100,000 at a reasonable rate of interest. The Directors required £30,000 to carry this out, and, with the assistance of his own personal guarantee, and with that of Lord Farrer, Mr. John Wood, Mr. Holland, and others of the large shareholders who came to his help, he obtained an offer of a loan of £30,000 for them for twelve months at 8 per cent. per annum from one of the Trust companies. The Directors refused this offer, as they were promised £50,000 at 6 per cent. Ultimately this arrangement fell through, and the Directors applied again to him (the speaker), having in the meantime had to borrow £20,000 at the high rates of interest mentioned in the Official Receiver's report. Mr. Rawson then obtained further loans, and negotiated the sale of the Company's business in France, which sale would have taken place, and the Company would not have gone into liquidation had it not been for the action of certain parties.

Mr. DUNCAN, as the official liquidator, also spoke, and, at the request of some of the shareholders, explained the present position of the Company. They had now sold the property for the sum of £8,600 in cash, £60,000 in debentures, and £5,000 in Founders' shares. These were very nearly the same terms as were offered before, because, although they were offered £20,000 in cash, yet they had to provide out of that certain heavy payments. They had gone a step further, and, with the consent of a large number of the creditors and debenture holders, they had been trying to work out a scheme by means of which something might still be saved for the shareholders; and there was a provision made by which the debenture holders would consent to be paid out in French paper for their credits against the Company, plus the interest at par. If this scheme were passed, the ordinary creditors would consent, also, to take paper in the shape of first mortgage debentures on what assets would then belong to the resuscitated Company, because the Company would continue, in a sense, as a Trust Company for receiving the results from Paris and distributing the same. They had also secured the consent of the Foreign and Colonial Company to postpone its claim on £50,000 of its holding in shares until the Ordinary shareholders should have received 5 per cent. Of course, such a prospect as 5 per cent. dividend on the Ordinary shares seemed a long way off; but it was not altogether impossible of realisation, judging from the appearance of things at present. In fact, he thought it was quite possible that they might still see something back on their shares. Altogether, the scheme was well worthy of their consideration; for it came to this—that if the process could have made profits in their hands, with the assistance of £80,000 more of cash put into it, then they would get more than half the same results; in fact, the scheme would be a bigger thing in reality, in the future, than it would have been in their hands.

After various questions had been answered by Mr. Duncan, Major Jones and Mr. Rawson, Mr. STRETTALL asked what the total amount of the commissions and fees were that Mr. Rawson had been paid for the work done by him.

Major JONES (late Chairman): Not a penny.

The OFFICIAL RECEIVER confirmed this, and Mr. Rawson stated that he would like to mention, to avoid misunderstandings in the future, that he had received a call of 10,000 Preference shares at par for certain services rendered. He has handed over the major portion of this call to parties who had, he considered, been badly dealt with by the Company, and had returned the balance of the call to the Company. He had not actually received his out-of-pocket expenses, with the exception twice of his ticket to the North of England.

At the request of Mr. Duncan his appointment as liquidator to carry out the scheme was adjourned till Wednesday, the 20th inst.

Hove Electric Lighting Company (Limited).

The following is the first report of the Directors of this Company, which is to be presented at the annual general meeting to be held at the Town Hall, Hove, Sussex, on Tuesday next, at three o'clock :—

The Directors congratulate the shareholders upon the success which has attended the operations of the Company to the present date. The balance-sheet accompanying the report is made up to September 30th last, and is only an interim statement, to be followed early next year by the accounts up to December 31st, prepared in the form required by the Board of Trade. The result of working up to September 30th, after debiting to revenue a proper proportion of the administration charges, from January 1st, when the lighting was practically commenced, is a debit balance of £264. 10s., a result which, in a new enterprise, must be considered satisfactory. Since about the middle of September the working account shows a steadily-increasing net profit each week, and the balance at the debit of the profit and loss account on September 30th has since been reduced considerably, and the Directors hope will soon disappear. The contract with Messrs. Crompton and Co. (Limited) was sealed on August 19, 1892, and by November 28th following a temporary station had been erected, with the necessary plant and machinery, a considerable length of permanent mains had been laid in culverts and casing, and the supply of electric current to the public was commenced, and has continued ever since without interruption. Since that date the mains have been extended in various directions to meet the public demand, until the total length now laid exceeds 6¼ miles. The erection of the permanent station by the contractors is rapidly approaching completion. The number of houses and buildings connected up to the Company's mains is 82, and, including arc lamps and sockets, the number of lamps attached to the system is equal to 6,169 of eight candle-power. Applications for the light are also steadily increasing, and it is confidently expected that the Company will soon be doing a large and remunerative business. From the station report of November 23rd, the net profits of the Company, after providing for all administration and other charges, amounted to £18. 15s. 0d. for the week. On September 30th last, the Company had issued 3,290 shares, and a few more have since been taken up, but the large amount due to contractors and others makes it a matter of urgent necessity that further capital should be obtained forthwith. The Directors have appointed Mr. Robert Payne (chartered accountant) to be Auditor.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns for the week ending December 3, 1893, were £902, as against £907 in the corresponding period of last year, being a decrease of £5. The total receipts for the half-year amount to £18,221, as against £18,043 for the corresponding period, 1892, being an increase of £178.

COMMERCIAL CABLE COMPANY.—A quarterly dividend of 1¾ per cent. on the outstanding stock of this Company is declared payable on January 2nd next to stockholders on the books on December 21st. The transfer books of the Company will be closed from December 21st to January 2nd, inclusive.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of November are £3,300, as compared with £3,262 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for November amounted to £2,442, as compared with £2,137 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of November amounted to £60,995, as against £60,491 in the corresponding period of last year, or an increase of £504.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of November amounted to £40,247, as against £40,851 in the corresponding period of 1892.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for November amounted to £21,600, and from January 1st to November 30th to £248,400. In the corresponding periods of 1891 and 1892 the amounts were £260,200 and £245,600 respectively.

RICHARD HORNSBY AND SONS (LIMITED).—The ordinary general meeting of the shareholders of this Company was held at Cannon-street Hotel, E.C., on Monday last.—Mr. James Hornsby, in moving the adoption of the report, stated that severe competition, with lowered selling prices and other unfavourable circumstances, had had much to do with their unfavourable balance-sheet, but they were doing their best to meet all the changing requirements of the times. They had met the falling off in business caused by the general depression as well as they could, and had been greatly helped by the increased demand for their goods in South America. The item in the balance-sheet of sundry debtors, £136,037, was about £5,600 more than last year; but last year's amount was unusually low, being £9,000 less than the previous year, so that that amount was in no way excessive. Those debts were thoroughly good, and were being well collected, over £70,000 having already been received.—The report was adopted.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—A special meeting of the shareholders, called to consider the necessity of increasing the subscribed capital of the Company, took place at Crescent-chambers, Morecambe, on Wednesday last week. After statements by the Directors and secretary as to the amount of outlay the Company was committed to for the extensions of plant made this year, and the position in other respects, nearly 1,000 shares were subscribed in the room. One of the Company's engineers, we understand, took more than 500.

NATIONAL TELEPHONE COMPANY (LIMITED).—Notice is given that the transfer books of this Company will be closed from the 9th to the 22nd inst., both inclusive, preparatory to the payment of an interim dividend, the warrants for which will be posted on the 22nd inst.

NEW SHANGHAI ELECTRIC COMPANY (LIMITED).—An extraordinary meeting of the shareholders in this Company has been held, when the resolutions, previously passed, that the Company be wound up voluntarily, with the Directors as liquidators, were confirmed.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ending December 1st (after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company, Limited), were £3,469.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 813. - VOL. XXXII. FRIDAY, DECEMBER 15, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

THE supply of electrical energy from Deptford was last week once more impeded by a series of accidents. Unlike the recent difficulty at Bankside, where the failure of the field-circuit of one machine spread trouble through the remainder of the plant, the three mishaps at Deptford were practically independent. Unlike the Bankside accident, too, they did not arise from electrical causes, but were purely mechanical. And to push the contrast further, the Mordey alternators suffered from being banked together before suitable cut-outs had been fitted, the subdivision of units rendering no assistance, while the Ferranti plant failed to maintain the supply on account of the large size of the units, and the consequent fewness of machines.

THE chronicle of last week's misfortunes is as follows:—One of the two large dynamos, which used to be called 1,250 H.P., but which have proved to be nearer 1,750 H.P., was under repair; new armature coils for generating at 2,400 volts instead of 10,000 volts were being fitted. The spindle of one of the Corliss valves on the other set was damaged, and the engine had to be shut down. Another dynamo of 750 H.P. had been disabled during the week, something having fallen into the armature, wrecking the coils and bending the shaft. One of the 350-H.P. engines used for light-load work was at the time undergoing repairs to the governor. To add to the week's misfortunes, which were serious only because of their concurrence, the throttle valve of one of the large engines broke, and fouled the main valve. On Monday, Thursday, and Friday the supply was partially checked, and on Friday evening only two engines, one of 750 H.P. and the other of 350 H.P., were running until 9 p.m., when the full supply was restored.

IT will be remembered that the two 1,750-H.P. sets, with 12ft. 6in. armatures, occupy one quarter of the present engine house at Deptford, and about one-sixteenth of the whole space available for machinery. But thirty-two units of plant were never contemplated. One quarter of the present building was set apart for condensers for 120,000 H.P., and in the remaining half, four 10,000-H.P. alternators, with 45ft. armatures, were to be put down. The incomplete condition of the station does not, however, affect the number of divisions of the plant, for several sets that were at one time running at the Grosvenor Gallery are now in use at Deptford. It has been argued that far larger marine engines run continuously for weeks, under confined conditions of space. But the working conditions are altogether different, for the load at sea is comparatively constant, and the engine-room is not manned with the object of saving a decimal of a penny per horse-power hour, as in most electric supply stations. Had the load at Deptford been anything like that which might have been reasonably expected before the run of bad luck began, and had six or eight sets of 1,750-H.P. alternators been employed, such misfortunes as these could not have happened. The London Electric Supply Corporation has to do the best it can with its present plant, and our sympathies are with them and their engineering staff. But the accidents teach the danger of using large and few units of plant, and the importance, where alternators are used, of reserve machines, and of some efficient system of boxing in the armatures.

AT a recent meeting of the York Town Council the following rider was added, after a somewhat heated debate, to a report containing a reference to the electric lighting question:—"Whilst fully acquitting the Streets and Buildings Committee of any irregularity, this Council is of opinion that all expenses of its Committee on city business should be defrayed out of the rates of the city." The episode which gave rise to this categorical enunciation of an elementary municipal principle was the visit of an electric lighting sub-committee to a couple of central lighting stations at the expense of a couple of expectant contractors. After having been four years amassing information the sub-committee were still intent on getting more, and were not, as a member expressed it, "above being feasted with the not very distant object in view of those who feasted them obtaining some advantage." At the risk of being told, like the movers of the above mild censure, that we show "a supremely indifferent knowledge of what is carried on in the commercial world," we must congratulate the York Town Council on being the first to take action in regard to this growing practice of free trips and light lunches. Contractors, it is pretty obvious, cannot, in these days of keen competition, afford to neglect anything likely to lead to the securing of a contract, and if free trips and lunches contribute to that end, these will be provided, we may be sure. It is not for contractors to commence by taking up a puritan attitude: *que messieurs les conseillers commencent.*

The commutation of alternate currents is a subject which appears every now and then to attract a large share of attention. We print in our correspondence columns this week a suggestion by Captain J. H. Thomson of a new method of rectifying these currents, so that they may be used for charging purposes. However ingenious this method is, there seems no prospect that it will be successful. It involves the use of a commutator revolving synchronously with the alternations of the current, and it also needs two condensers of large capacity capable of withstanding high potentials. These adjuncts are quite sufficient to condemn the method, but a more serious defect still arises from its inefficiency. It may be true that good condensers for high potentials can be easily procured at a moderate cost. But, however good they may be, they absorb energy due to the passage of the current through them. The present method suggested for charging cells would involve as much waste of energy in the condensers as is usefully taken up by the cells under charge. In order to charge a battery of 50 cells, it is apparently necessary to have a 2,000-volt circuit and two condensers, each taking the full charging current at 1,000 volts. Now, experiments which have been published on condensers have shown that the power they absorb is about one-fortieth part of the product of the voltage at the terminals into the current in amperes flowing through. The voltage on the condensers is so much greater than that on the cells that the power absorbed by the former is quite comparable with that given up to the latter. Under these circumstances the method is hardly efficient or economical.

Stepping into a train yesterday on the "underground" we observed that the long-promised penny-in-the-slot electric reading lamps were at length in position at the four corners of the compartment. Inserting the necessary penny and pressing the button (the larger one), we noticed nothing particular to happen, and certainly no light shone forth. Presently, however, we detected the lower limb of the circular coin projecting from the bottom of the apparatus; and taking this as an indication that there were no watts on supply, we transferred the penny to the opposite lamp. This time a radiance filled the corner of the carriage. We had heard that a light of 20 c.p. would be supplied. As it is a projected light, there may be special ideas as to the way it ought to be photometered. Certainly it did not look like a light of twenty candles. Still, there shone upon us a soft and steady light, bright enough to enable the smallest type of printing to be comfortably read, yet not dazzling. A light of twenty candles would, probably, be far too dazzling for the purpose. But is it not monstrous that the passenger should be mulct in pence for necessary light? As a daily contemporary some time ago observed, we shall some day be asked to "put a penny in the slot" in order to stop the squeaking of the railway carriage wheels by supplying them with a small quantity of a superior grease.

If dynamo makers still continue to use annealed wrought iron forgings for magnet bars and yokes it is not for lack of invitations to try special cast steels and peculiar iron castings. We have received from a well-known electrical engineer a set of lithographed curves which he has received from a firm of iron-makers, and which profess to set forth the advantages of a wonderful kind of cast iron. The B H curve of wrought iron is given, showing a positive induction of 16,000, with a positive magnetising force of 58, and a negative induction of 14,400 for a similar negative magnetising force. Singular as such a brand of wrought iron may be, it is a pity to use it for purposes of comparison; it should be kept in a museum. But the "special" magnet material is no less remarkable, for while the B H curve practically coincides with that of wrought iron for the positive magnetisation at 16,000, it runs up to about 16,700 for the same negative magnetising force. This æolotropic permeability might be useful for making so-called unipolar dynamos, and prepares us for the announcement of a queer kind of steel, which will gratify mathematicians by the realisation of a single free magnetic pole.

Aberdeen.—The scheme for experimental street electric lighting is to be proceeded with at once.

Bristol.—The electric light is now being supplied to all the streets comprised in the area agreed upon for the initial undertaking.

Obituary.—We regret to announce the death, on the 4th inst., of Mr. Bryan Donkin, at the age of 84. Mr. Donkin was well-known among engineers, especially in connection with his extensive researches in steam-engine practice and economy.

The Gauss-Weber Memorial.—The subscriptions received for the erection of a monument in honour of Gauss and Weber, at Göttingen, have reached a total of £1,110. This figure does not include sums promised but not yet paid, which will bring up the total to £1,250.

The Government and the National Telephone Company.—It is stated that there is no prospect of the agreement between the Post Office and the National Telephone Company being laid on the table of the House of Commons this session. Mr. Arnold Morley promised it some time in the autumn session, but it has not made its appearance, nor is it likely to do so before the House adjourns.

Use of the Telephone by the Police.—On November 5th, for the first time, the Hertfordshire constabulary brought into requisition telephonic communication between Hitchin, Baldock, and Royston, three of their principal stations. By order of the County Council the whole of the police-stations in the county are to be brought into direct communication with each other. The wires are fixed to the various telegraph posts, thus considerably curtailing the expense to local authorities.

Royal Society Medals.—We learn from a French contemporary that the Rumford Medal of the Royal Society has been awarded to Prof. D. E. Jones for his translation of Hertz's researches, and that "Lord George Gabriel Stokes" has received the Copley Medal. Never before, says our contemporary, has a translation been so highly recognised. Never before, we echo, has our contemporary's translator so thoroughly surpassed himself.

Novel Form of Electric Railway Car.—It is intended to introduce new passenger cars on the Brighton Electric Railway of a very novel shape. These cars will be built in the form of a yacht, with a "saloon" in the middle. It is thought by the projectors that this method of taking a marine trip will recommend itself to excursionists; but whether the remote chance of the cars taking to the water had anything to do with the choice of this shape, we are unable to say. The Brighton electric railway is shortly to be extended to Rottingdean.

Accident to a French Telegraph Line.—A somewhat curious accident occurred recently to the Tours-Châteauroux telegraph line. One of the poles was blown down and fell across the

Digitized by Google

railway. A train coming along, the wires got entangled with the wheels, but the driver did not notice the fact until he had pulled down a long length of line. This may perhaps be taken as an illustration of the disadvantage of always running slow trains, the habit so grows upon the drivers that the braking effect of a few miles of telegraph wire coiled round the axles is scarcely sensible to them.

Cable Interruptions :

	Date of Interruption.
Cayenne-Paramaribo	October 25th.
Bissao-Bolama	November 24th.
Cayenne-Vizeu	November 25th.
Jamaica-Colon	November 25th.
Kotonou-Accra	December 4th.
Lagos-Brass	December 4th.
San Domingo-Martinique	December 10th.
Haiphong-Hongkong	December 11th.
Singapore-Saigon	December 11th.

The General Electric Company of America.—According to *Electricity*, of New York, the business of this Company "has sunk to almost nothing, its factories are almost as silent as a graveyard at midnight, and its *employés* have few duties except attendance upon committee meetings. There is no head to its affairs, no policy, and consequently no energy. It is like a ship at sea with a discredited captain and broken-down engines." In a subsequent issue the same journal states as the result of investigation at the Lynn and Schenectady works that the Company has 2,100 men at work on half time, against a high-water mark of 7,500 men at full time.

House-to-House Electric Light Supply Order, 1889.—In an order, dated the 6th inst., the Board of Trade give notice that they have revoked the House to House Electric Light Supply Order, 1889, in so far as it relates to the area of supply specified in paragraph (*b*) of the first schedule to the Order, as from December 1, 1893. The scheduled streets in area *b* were Ladbroke-grove, Ladbroke-grove-road (part of), Uxbridge-road, Royal-crescent, Lansdowne road, Lansdowne-crescent, Cornwall-road (part of), Lancaster-road (part of), Elgin-crescent, Elgin-road, Ladbroke gardens, Archer-street, Colville-square, Powis-square, Cambridge and Oxford-gardens, Bassett-road, St. Mark's-road (part of), and St. Charles' square.

A Telegraphic Reminiscence.—Inspector William Craig, has just sent in his resignation to the Directors of the Great Western Railway, after over half a century's inspection of traffic at Paddington Station; he was in 1845 one of three servants of the Company who took part in the first application of the electric telegraph to the detection of crime. The Company had not then adopted the telegraph, but there was an experimental wire to the Slough signal box, which was exhibited as a sort of shilling wonder. A message was received at Paddington to "watch Tawell," a man suspected of murder. Tawell duly reached Paddington, was apprehended, and in due time executed.

New Books.—Messrs. Macmillan and Co. are about to publish a revised and enlarged edition of "Elementary Lessons in Steam Machinery and the Marine Steam Engine," by Messrs. Langmaid and Gaisford, instructors on H.M.S. "Britannia." It will be followed by other works, constituting a Britannia Science Series. Among those already in hand may be mentioned "Physics for School Use," by Mr. F. R. Barrett, Mr. A. E. Gibson, Rev. J. C. P. Aldous, and others; a "Physics Notebook," by Messrs. Gibson and Aldous; "Trigonometry for Practical Men," by Mr. W. W. Lane; and "Geometrical Drawing, Perspective, and Mechanical Drawing," by Mr. J. H. Spanton.

Institute of Chemistry.—Prof. W. A. Tilden, F.R.S., opened the new laboratories of the Institute of Chemistry of Great Britain and Ireland, at 30, Bloomsbury-square, W.C., on Friday last. Much care has been expended on the construction of the new buildings, which appear to be admirably adapted for the purposes for which they are designed. Prof. Tilden, in declaring the laboratory open, explained that the Institute insisted upon a course of training extending over three years, at the end of which time a student could become an associate if he had satisfied the examiners in the various branches of study prescribed. Another three years' study was necessary before an associate could become a fellow of the Institute. There were now 731 fellows, 104 associates, and nearly 200 registered students.

Telephone Tubes in the City.—At the last meeting of the City Commissioners of Sewers a letter was submitted from the City of London Electric Lighting Company, asking the Commission to end the present deadlock as to the telephone tube question by giving their consent as required by the Telegraph Act, 1891. The Company first controvert the assertion that the tubes were laid simultaneously with the electric-lighting apparatus without the knowledge of the Commission. With reference to the conditions which the Commission sought to impose on the users of the tubes—to grant a telephone service within the City at £8 per annum—the Company were informed by the highest authorities that that was incompatible with an adequate return on the capital invested. The Company was erecting plant, &c., to supply 25,000 customers with electric light. If the revenue derived from telephone tubes be reduced to please 3,000 citizens, it could only be at the expense of 25,000. In the meantime, the tubes were lying idle, neither benefiting electric-light users nor telephone subscribers. The letter is under consideration.

Walsall.—At the Town Council meeting on Monday last a special report was presented with regard to electric lighting in the borough. The committee "being advised that a properly-constructed plant would be no danger to the consumers," recommended the adoption of the high-pressure system, and that the tender of the Electric Construction Company be accepted to erect the plant for £10,003. They also recommended that contracts be made with Messrs. Bumsted and Chandler for engines, and Messrs. H. and T. Danks for boilers, and that steps be taken to obtain the necessary sanction of the Board of Trade and the Local Government Board. The resolution was carried. The Streets Committee also submitted a special report from Mr. F. Brown, electrical engineer to the Corporation, stating that the electric tramcars had worked very satisfactorily. There had been difficulty with some of the lengths, but they had been remedied, and the line was in a good condition throughout. The number of passengers in the borough had increased from 1,871,816 in 1892 to 2,245,660 in 1893, and the public appeared thoroughly satisfied with the appearance of the trams as compared with the old steam traction engines.

Defective Flywheels.—An article by Mr. W. Stuart-Smith, in a recent number of the *Electrical World*, of New York, on the subject of defective flywheels, calls attention to a point of the greatest importance. In the discussion of flywheel accidents it is almost invariably assumed that the cause is due to tangential strain, which involves the further assumption of an increased speed of the engine, and a defective governor is held up as the initial cause. Mr. Stuart-Smith points out that a sufficient cause for such accidents is a want of symmetry in a wheel with respect to a plane perpendicular to the shaft. This may follow from the construction of the wheel itself, or from its being so mounted as not to run true. From the design of flywheels they are incapable of resisting any considerable lateral strain, and there is every reason to believe that many accidents, ascribed without sufficient evidence to defective governors, have been due to the cause referred to. One fatal mistake which is commonly made is to assume that a wheel which is in balance when at rest will also be balanced at a high speed. There are numerous deforming forces set up by the motion which may cause deformation sufficient to rupture the rim of the wheel.

Proposed Regulations for Accumulator Works.—The Departmental Committee appointed by Mr. Asquith to inquire into white lead and the allied industries have issued their report, which is signed by Messrs. Edward Gould (Chairman), A. Dupré, Thomas Oliver, H. J. Cameron, and H. J. Tennant. The Committee were directed by the Secretary of State to inquire (1) into the conditions under which lead smelting, the working of blue lead, and the production of white lead, red lead, yellow lead, and litharge are conducted, with the object of diminishing any proved ill effects on the health of the workpeople engaged therein; (2) as to whether the special rules which already exist with regard to the manufacture of white lead are sufficient; and (3) to suggest any precautions necessary to the industries specified for the protection of life

Digitized by Google

or health. The inquiry was extended into England, Scotland, and Wales, and the Committee visited 46 works, and examined 184 witnesses. Its recommendations as regards electrical accumulator works are summarised as follows:—The adoption of respirators and overalls for mixers; the provision of gloves and aprons for rubbers; the provision of bath and lavatory accommodation, with a plentiful supply of hot and cold water, soap, nail-brushes, and towels.

Electric v. Steam Railways.—A lecture was delivered last Monday evening, before a crowded audience, in the Chemical Theatre of the Owens College, Manchester, by Dr. Edward Hopkinson, on the subject of electric railways. During the lecture some instructive details were given of the comparative cost of electric and steam power. The City and South London line had enabled experiments to be made on the efficiency of the railway system as a whole. The loss in the line was about 11 per cent. of the electrical power generated, and the efficiency of the locomotives as a whole was 70 per cent; thus the electrical efficiency of the entire system was 62 per cent. The cost of working, including all charges, during the last half-year, was 6½d. per train mile. It was perhaps hardly a fair comparison to compare the cost of working such a line as the South London line with the cost of steam traction on other lines, inasmuch as steam could not possibly be used in the tunnels, only 10ft. 6in. diameter, in which this line was constructed, but the comparison was not uninstructive. Taking the Mersey Railway, where the gradients and nature of the traffic were similar, according to the published returns of the Company the cost of locomotive power was 14d. per train mile, *i.e.*, more than double the cost on the South London line, but for a train weighing between four and five times as much, but capable of carrying only 3½ times the number of passengers; thus the cost of steam traction per ton mile of train was about half that per ton mile of train for electric traction. But it was not on the cost per ton mile that the success of a passenger line depended. The real basis of comparison was the cost per passenger mile, and here electric traction had great advantage over steam.

What is Electricity?—"To the metaphysical mind on the one hand and to the confident ignoramus on the other," says the *Electrical World*, of New York, "the mysterious nature of electricity offers a fruitful subject of speculation. To the latter, especially, it seems a reproach that the true nature of electricity has not long before been made manifest, and he is always prepared to dash off an explanation with much more confidence than Newton proposed his theory of gravitation. It seems inexplicable to the public at large that the mystery surrounding electricity is not dispelled. The successful business man, who prides himself upon always getting to the bottom of everything, cannot understand why this one problem, as he believes, remains unsolved, and, perhaps unconsciously thinks that if his work had been in this direction, his 'hustling' abilities would have produced a more favourable result than attained by scientific theorists. It does not seem to occur to those who are impatient to have the great question, What is Electricity? answered, that we are in just as dense ignorance as to the mechanism of other phenomena. Gravitation, light, heat and chemical action are in the same category of scientific mysteries and have had centuries more of thought bestowed on them than has been devoted to the new agent. While it now seems that we may be on the threshold of one of the greatest discoveries of the human mind, yet it is possible and even probable that the knowledge of man may never be permitted to extend to the entire solution of the problem, for it is the very problem of the universe itself. True, we may demonstrate the exact relation between electricity and magnetism, and may satisfactorily connect these with other phenomena, and even obtain a working hypothesis that will answer all scientific needs, but the ultimate solution may for ever evade the human mind. Whatever we do learn, however, will not be through the speculations of metaphysicians or the guesses of tyros, but through physical investigations."

Heliotropism produced by Electric Sparks and Arcs.—In a Paper read before the Royal Society last month, Prof. G. J. Romanes, F.R.S., describes his researches on the effects of intermittent light, such as that produced by an electric spa discharge, or by an arc light and instantaneous shutter, upo the growth of plants which exhibit heliotropism. Th phenomenon is very common in the more highly-develope organisms of the plant world; it may be defined as th bending or twisting action upon the growth of stalks an stems, such as the "staircase effect" in the convolvulus, upo their exposure to a source of light. The electric sparks wer made either with a Wimshurst machine, induction sparks, c by means of the following contrivance:—From the bindin screws of the condenser of a large induction coil copper wire were led to a cup of mercury, where, by means of an electr magnet suitably actuated by clockwork, a current was close and opened at any desired intervals; each break was, ther fore, accompanied by a brilliant spark. A thick plate of gla was interposed between the seedlings and the electric apparatus. In all the experiments here described the plan employed were mustard seedlings (*Sinapis Nigra*), previous grown in the dark until they had reached a height of betwe one and two inches. Comparative estimates were formed by usi the same pot of seedlings: during the first half of a compa tive experiment half of the seedlings were protected from t light by a cap of cardboard covering half the pot; during t second half of the experiment this cap was removed, and t pot turned round so as to expose the previously protect seedlings to the influence of the light. From the experime it would appear that the heliotropic influence of electric spa (or flashes) is greater than can be produced by any ot artificial or natural source of illumination. But, strange relate, this mode of lighting appears to be absolutely un companied by the production of chlorophyll—the green colo ing matter in the stems and leaves of plants.

The Field Electric Railway Patent.—One of the m important suits ever brought before the Federal Courts of t country, in its relations to the electric railway industry, says the *Electrical Engineer* of New York, just been arg before the Courts in New York. The case is that of Electric Railway Company of the United States *v.* the Jam and Brooklyn Road Company, for infringement of lett patent No. 407,188, granted July 16, 1889, to Stephen Dud Field, for "Improvement in Electric Railways." Only on the claims of the patent is involved in the suit, namely, first, which is as follows:—"The combination, substanti as hereinbefore set forth, of a stationary dynamo electric ge rator driven by a suitable motor, a circuit of conductors c posed in part of an insulated or detached section of the line rails of a railroad track, a wheeled vehicle movable upon along said insulated section of track, an electro-magnetic mo mounted upon said vehicle for propelling the same and incluc in said circuit of conductors, and a circuit-controlling dev placed upon said vehicle." On March 10, 1880, Mr. Field fi his application for letters patent. The application was sc brought into interference with subsequently filed applicatio of Ernst W. Siemens, Thomas A. Edison, George F. Gre and Thomas Hall, and the contest was conducted with a pe sistency seldom, if ever, equalled in the history of the Pate Office. In all of these interferences, Mr. Field was decided be the first and original inventor of the subject matter ther and particularly of the combination of elements in the fi claim of the patent in suit. In 1883, prior to the settling the claims of the various contestants, the Field interest a Edison interests decided to pool their patents. Subsequent however, the Edison interest purchased a controlling inter in the Sprague Electric Railway and Motor Company, a co petitor with complainant; and a suit at law was necessary compel the attendance of the Edison Directors at the meeti of the Company to which both parties had assigned th patents. The Edison Directors refused to advance more mo for the carrying on of complainant's business, though the Fi Directors offered to advance an equal amount; and to s complainant corporation from going into a receiver's hands was necessary for it to sell back to the Edison interests t patent rights originally received from them. It is furt claimed, and admitted by counsel, that the real defendant the case is the General Electric Company, the successor to t Edison Electric Light Company.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 136.)

Waste Power.—The elastic forces of inertia, which under certain circumstances form a part of the total resistance, are modes rather of diverting than of wasting the energy which is expended against them, inasmuch as they are perfectly elastic and reversible. On an accession of speed they absorb energy and divert the power from its directly useful work, but on a return to the original speed they restore the energy which they formerly absorbed and expend power over and above that directly developed by the source of energy itself. Not so, however, with the other resistances which prevent the total power from going directly to its work, for these are prejudicial, and actually waste the energy which they absorb. It f_1 represents the total of these inelastic and prejudicial resistances, and v is the velocity with which their point of application is overcome, in feet per minute, then the horse-power wasted against them will be

$$\text{H.P. (wasted)} = \frac{f_1 \cdot v}{33{,}000}. \quad . \quad . \quad . \quad (26)$$

To minimise this waste of power is one element in engine design and construction; firstly, because this waste is a direct expenditure of energy from the source which must cost money: secondly, because the secondary actions arising from this waste are liable to cause injury to the engine details; thirdly, because the presence of waste involves the construction of a larger and more expensive engine in proportion to the amount of waste going on. Wasted power is dissipated in some one or other form of radiation—either as waves of sound, as vibration communicated to the foundations and immediate structure, or as heat generated in the places where the resistances occur. Sound and vibration are liable to become [illegible] nuisances in the eyes of the law; heat is liable to cause sufficient expansion of the bearings, &c., where it occurs, to break down the machinery. There are several ways of [illegible] these wastes:—

(1) By minimising the coefficient of friction of the moving parts where pressure occurs, as by lubricating those parts.

(2) By carefully adjusting the distribution of pressures on relatively moving parts, so as to avoid excessive concentration, want of balance, or suddenness of change in direction or magnitude of the pressures.

(3) By locating the pressures at such points that there is as small velocity as possible against them in the normal working of the parts where the pressures occur; as by selecting small diameters for journals for shafting, or by the use of ball or roller bearings.

Useful Power.—The action of the engine in overcoming the resistances of the machine upon which useful work is done, constitutes the useful power. This power is the difference between the total power and the sum of the stored and wasted power, and is equal to

$$\text{H.P. (useful)} = \frac{f_2 \cdot r}{33{,}000}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (27)$$

where f_2 is the useful resistance and r is the velocity with which it is overcome, in feet per minute. This power is not [illegible] less than the total power which is being developed by the engine, as will be seen from the equation:—

Total power = Waste power + Stored power + Useful power. (28)

In which the stored power may sometimes have such a large negative value as to make the useful power greater than the total power developed by the engine. For this to continue, however, would necessitate a large store of energy; and since no engine is provided with stored energy enough to enable it to do more than a few revolutions of full work, it follows that in the long run the stored power may be taken as having no value. In such a case, we may write

Total power = Waste power + Useful power. . (29)

Every term being positive in value at all times, it follows that the ratio of the useful power to the total power cannot (over a long average) be greater than unity. In point of actual fact, this ratio cannot be so large as unity; but the closer it approaches this ideal value the more perfectly may the engine be considered to utilise the energy which is supplied to it. This ratio is therefore called the *efficiency* of the engine. It is usual to express this quantity as a percentage, in which case its limiting value is 100. In this series we shall express its fractional value by the symbol η.

Load.—The term *load* has several meanings in engineering. It is applied to the action of external forces upon a structure, in the engineering of structures and materials, and it is applied to the power which is taken from an engine or motor or other source of power. Usually the load on an engine is the mechanical horse-power which is, at any moment, being taken from the engine-shaft or pulley, but the term *total load* is sometimes used, as distinguished from this *external load*, to express the total horse-power which the engine is called upon to develop. In this sense load is another term for power, or, to be more correct, it is the condition of things which calls upon the power to develop itself. In an electric-power station there

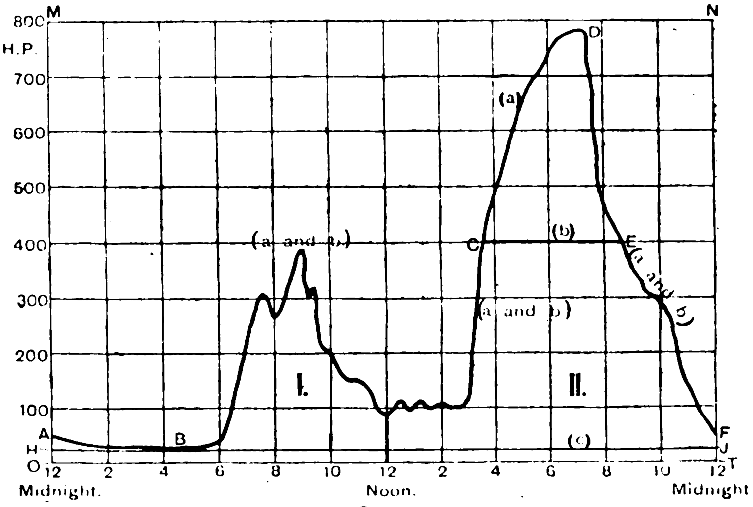

FIG. 2.

are many forms of load; there is, firstly, the external electrical load, or the electrical horse-power (E.H.P.) taken off by the mains; secondly, there is the sub-division of this into the several loads on the various generators and on the electrical storage plant, if any; thirdly, there is the load in mechanical horse-power which each of the generators imposes on its gearing, if any; and, lastly, there is the load, or series of loads on the engine and its accessory parts. Both the distribution of the loads at any moment of time, and their variation from time to time, have a very important bearing upon our study of motive power and gearing. It is convenient to construct a diagram or curve on rectangular axes of the variation of each load from time to time, and in some cases special recording instruments are arranged to automatically construct such curves.

Load Diagrams.—These curves are called *load diagrams:* and by means of them we may study the distribution of work and power in a generating station. They are commonly constructed on a horizontal axis of *time*, in hours or minutes or even days, and a vertical axis of *load*, output or power, as it is severally called. Fig. 2 gives a series of load diagrams (a), (b), (c), such as commonly occur at a power station. The curve (a) represents the variation of load on the whole station, throughout the day of 24 hours. If only one engine is run at a time, this curve will also be the load diagram of that engine in so far as it is running; but it may be divided up into

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

successive portions, such as I. and II., if two or more engines run consecutively. If the total load is taken by more than one engine at a time, say by two equal engines, then we may take the curve (*b*), which is partly level and partly coincident with (*a*), as the variation of load on one engine; while the surplus will be the load on the other engine. Lastly, if there are a great number of engines capable of being run at the same time, the load diagram of any one engine may be represented by the straight line (*c*). It will be seen that we have either large engines working at a small fraction of full load, or else small engines which largely remain idle during the time the station is at work. In neither case does the station do as much work in the day as it is able, as will be seen if we take the total power as O M, and draw a straight curve M N, representing what would occur if the station worked at full load all day.

Load Factors.—It is convenient to represent the ratio of the actual work done in a day, or an hour, or a year, to the total work which might have been done at full rate as a coefficient. This coefficient is called the *load factor*. It will be convenient in these articles to consider the following load factors:—

(1) The station load factor, or the ratio of the total work done by the station in any given time to the total work which it might have done had it worked at full capacity all this time without intermission.

(2) The dynamo load factor, or the ratio of the work done by any one dynamo in any given time to the work which it might have done had it worked at full capacity during the time it was actually running. Working without intermission is not here required.

(3) The engine load factor, which is determined in the same manner as (2), but for an engine.

(4) The plant load factor, or the ratio of the work done by any unit of plant in any given time to the total work it could have done had it worked at full capacity during the time without intermission.

Time spent in a state of absolute non-working will affect the values of the load factors in (1) and (4), but will not affect the values in (2) and (3). The difference between the station or plant load factor and unity may very conveniently be called the *factor of idleness*. The difference between the dynamo or engine load factor and unity may very conveniently be called the *factor of underloading*. The object in distinguishing between these two kinds of load factors is made evident when we study the questions of *prime* and of *working costs*.

Prime and Working Costs.—The principles which should guide the engineer in the design of an engine, dynamo, or power station, or indeed any machine for power production and transmission, are based upon economic laws, and not merely upon the physical laws of energy, stress, and strain. It is not sufficient to construct any plant so that it will work: it must be built so that it will *pay*. We cannot here discuss fully the economic principles which underlie engineering; but it will be necessary to briefly notice them. The total amount of money invested in the purchase and erection of plant and works, or the capital expenditure, is called the *prime cost*. The annual expenses, apart from capital charges, are usually called the *working costs*. These latter include works costs—such as cost of fuel, oil, &c., wages and salaries, repairs and maintenance, &c., rent, rates and taxes, and management costs. Economically, a plant may be said to pay when the surplus of the revenue, after all working costs have been paid, is equal to or greater than the sum of the normal annual value of the interest on the capital and the annual value of the depreciation of the plant. It is popularly supposed that a plant pays if there is *any* surplus of revenue over working expenses; but this is an error, since such payment is made for a short time at the sacrifice of capital in the long run. Interest on capital may be taken at the normal current rate, and may be defined as the percentage yield of capital when invested in a safe commercial market. Depreciation is expressed as a rate er cent. of the capital expended in plant, and is an allowance for the steady decrease in value of plant on account of wear and tear in ordinary work, and on account of the prospect of competition by improved patterns of plant. It must be observed that both prime and working costs tend to militate against any plant paying, since an increase of either will reduce the surplus of revenue, unless indeed there is a corresponding decrease of the other. It will in general be found that in order to decrease either of these factors of expense, it will be necessary to increase the other; and the essential business of the engineer is to design and arrange the plant in such a manner that the net expense shall be as low as possible,

The Economic Law of Design.—We have already said that no plant, or portion of plant, works with perfect efficiency. Let us suppose that it is proposed to improve a portion or the whole of any given plant with a view to increasing its efficiency, and thus reducing its expense in waste of power. This may be done, for example, either by substituting a better class of plant, or by paying for more skilled labour in looking after the plant, or by minor alterations in the existing plant, such as working it with higher pressure steam or different quality steam or by raising or lowering the chimney of the boiler furnaces. Let HP be the power which will be saved from waste by this process of change, and let C be the total cost in pounds sterling which the change involves either directly or indirectly, any saving which is made in the prime cost on account of the fact that a smaller engine may be used being set off against this cost by subtraction from it. We may say, then, that C is the net prime cost of the alteration; and let A be the annual cost of an amount of power equal to that which it is proposed to save. If instead of affecting the alteration we invest C in some commercial market, we may get B pounds sterling in the shape of dividend, but we lose the A pounds on account of waste of power. Now if A is greater than the current average value of B, it will clearly be advantageous to effect the alteration; while if A should turn out to be less than B, it will be more profitable to abandon the proposed alteration, because it will not yield a profit equal to the market value. Again, if a small alteration will yield a greater saving, A, than the interest, B, on the capital, C, it may happen that a more extensive alteration may be carried out, so as to yield a still greater advantage. But it is also evident that the limit, beyond which it will not pay to carry out any alteration, is that point where the annual value of the saving in working costs is exactly equal to the sum of the annual depreciation and the annual interest of the capital which the alteration would require. Suppose, for example, that the annual interest on capital may be taken at 5 per cent., and that it is proposed to spend £200 on a condenser for a steam engine, the depreciation and extra repairs being taken at 5 per cent. also. Then, if we have the condenser, we must spend £10 per annum on repairs and on account of depreciation; but we may save £30 in the engine expenses. While if we do not have the condenser, we shall only get £10 interest on the money. Here, since the annual interest plus the depreciation £(10+10) is less than the saving in annual expenses, £30, there is an advantage of £10 in having the condenser. In most cases there are several indirect costs and savings to be taken into account as well as the direct sums here considered, in which cases it will be a good plan to draw up a balance-sheet, with amounts debited and credited to the proposed alteration. In many other cases it is quite impossible to determine the money value of any alteration in design or in the character of the plant; and experience alone can be relied on to guide towards the best practice. This question has been worked out in *The Electrician*, Vol. XXIX., p. 248 in an article by the author on "Thomson's Law of Economy," and it was there shown that *the most economical design in any case is that in which the annual interest on the cost of any small improvement in the efficiency of the plant is equal to the annual saving of expenses which would result from that improvement being adopted*. Where the money values are determinate every effort should be made to obtain them correctly and fully; where they are indeterminate, the choice must rest upon experience assisted, it may be, by a series of carefully conducted experiments.

(To be continued.)

THE ALTERNATING CURRENT ARC.

To readers of our excellent contemporary, *La Lumière Electrique*, M. André Blondel is already well known for several valuable researches on the nature of the alternating-current arc. Some further researches by him have quite recently been published in the same journal, and the numerous curves which are given appear to completely describe the phenomena of the alternating arc under various conditions.

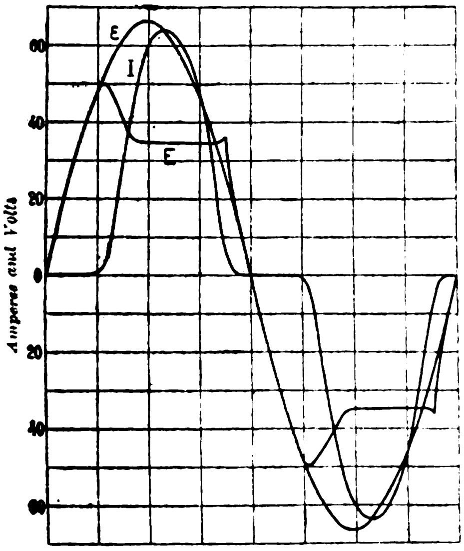

FIG. 1.—Solid carbons, non-inductive circuit. $l = 2$mm., $R = 0·10\ \omega$, $L = 0·0007\ h$, $\epsilon = 44·5\ v$, $E = 32·7\ v$, $I = 36·9\ a$, $\eta = 0·77$.

As in his previous work, M. Blondel employs a photographic method for recording the law of variation with time of the current through the arc, and of the voltage at the terminals of the carbons. His apparatus consists of a couple of d'Arsonval

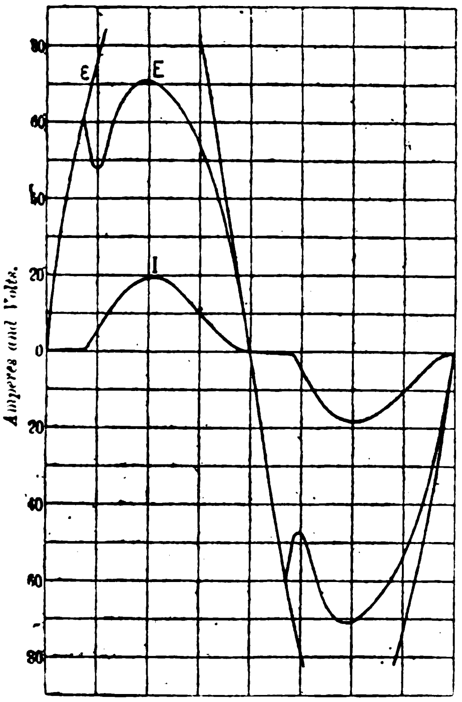

FIG. 2.—Jablochkoff candle (hissing arc), non-inductive circuit. $l = 5$mm., $L = 0·0007\ h$, $R = 2·70\ \omega$, $\epsilon = 72·5\ v$, $I = 11·1\ a$, $E = 53·3\ v$, $\eta = 0·91$.

galvanometers, one placed in the current circuit and the other in a potential circuit shunting the arc. Each of these circuits is periodically made and broken by means of a revolving contact maker attached to the shaft of the armature of the alternator. The mirror of each galvanometer reflects a ray of light on to the surface of a cylinder covered with photographic paper; and this cylinder is rigidly attached to the brush holder of the revolving contact maker, and turns with it.

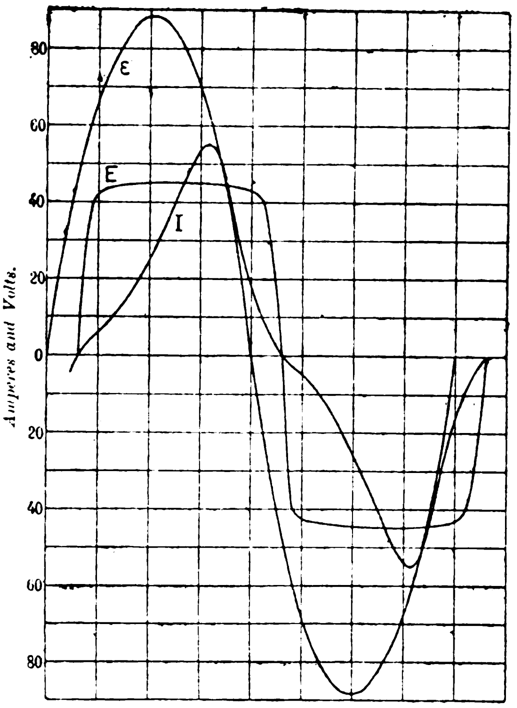

FIG. 3.—Solid carbons, inductive circuit. $l = 3$mm., $R = 0·10\ \omega$, $L = 0·0028\ h$, $\epsilon = 63\ v$, $E = 40·8\ v$, $I = 30\ a$, $\eta = 0·88$.

The result is that the photographic curves obtained on the cylinder show the way in which the current and potential vary with the time. After detailing a number of experiments which prove that his apparatus really acts as stated, M. Blondel proceeds to give a number of interesting curves showing how the shape of the current, or potential, curves is dependent on the character of the carbons, the inductive nature of the external circuit, and on other such circumstances. Of these curves we

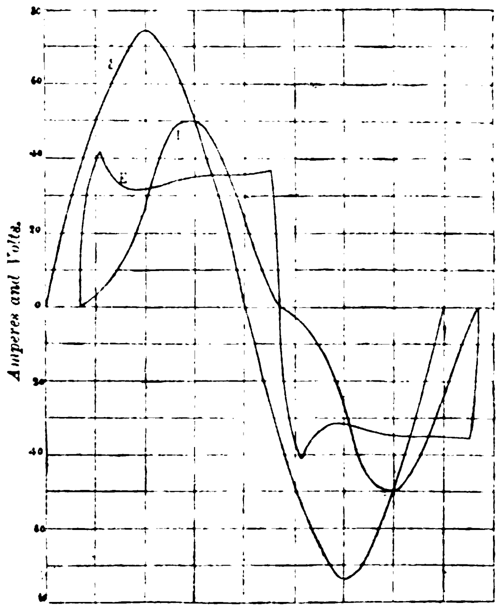

FIG. 4.—Solid carbons, inductive circuit (hissing arc). $R = 0·10\ \omega$, $L = 0·0038\ h$, $\epsilon = 51·5\ v$, $E = 31·8\ v$, $I = 29·8\ a$, $\eta = 0·86$.

have only space to reproduce a few of the more interesting. In all those given below the curve ϵ represents the electromotive force of the alternator, that marked E denotes the voltage between the carbons of the arc, while that marked I denotes the current through the arc. L is the self-induction of the

Digitized by Google

external circuit in henries, and R is its resistance in ohms, l is the length of the arc in millimetres, and η is the *power factor* of the arc, that is the ratio between the real power in watts absorbed by the arc and the apparent power absorbed obtained by multiplying the voltage on the arc by the current in amperes. This power factor in some cases is as low as 0·70. For silent arcs the value lies between 0·88 and 0·95, but for hissing arcs lower values generally obtain. Some tests made by Prof.

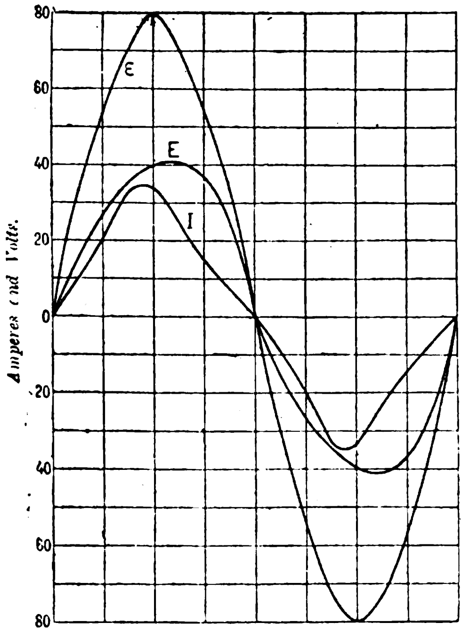

Fig. 5.—Cored carbons, low voltage, non-inductive circuit. l=2·5mm., R=0·40, ϵ=54·5v, L=0·0007h, E=27·9v, I=36·1a, η=0·93.

Ayrton and Dr. Sumpner, published in April, 1891, before the Royal Society seem to show that with a hissing arc the power factor may be as low as 0·50 for an alternating current whose frequency is 100 periods per second. M. Blondel was not able to obtain any case in which the power factor was as

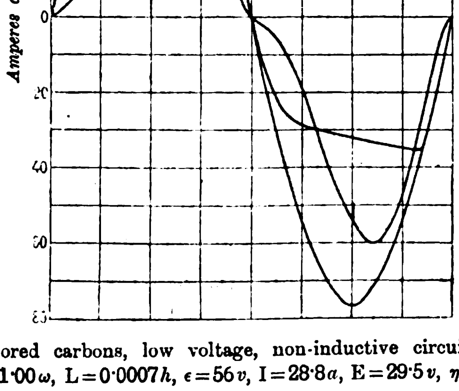

Fig. 6.—Cored carbons, low voltage, non-inductive circuit. l=4mm., R=1·00ω, L=0·0007h, ϵ=56v, I=28·8a, E=29·5v, η=0·95.

low as this, and attributes his failure to do so to the fact that the frequency of the current he used was different from that used by the English experimenters. It will be seen that the shape of these curves is dependent to an extraordinary extent on the character of the external circuit. We also notice that while the current curve is in general a simple zigzag in shape when the arc is silent, when the arc is hissing the current curve

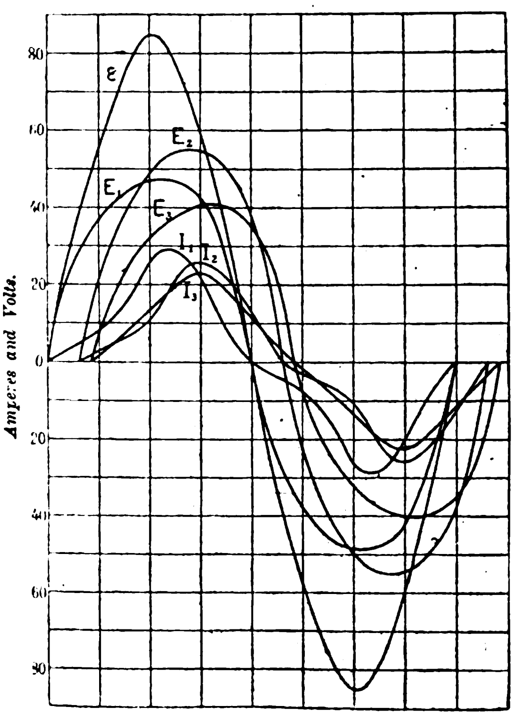

Fig. 7.—Cored carbons, low voltage. No. 1. Non-inductive circuit. l=9mm., R=1ω, L=0·0007h, ϵ=60·5v, E=35·8v, I=16·5a, η=0·95. No. 2. Inductive circuit. l=12mm., R=0·10ω, L=0·0046h, ϵ=60·5v, E=41·3v, I=15·5a, η=0·94. No. 3. Inductive circuit. l=5mm., R=0·10ω, L=0·0094h, ϵ=60·5v, E=31.1v, I=14a, η=1·00.

tends to become discontinuous, so that for certain portions of the period the current is either zero or very nearly so.

M. Blondel's conclusions from his experiments may be summarised as follows :—

1. The phenomenon of the alternating arc is more complex than is generally believed, and it cannot be described by reference to a single typical case. The differences in the effects produced by various dynamos can in most cases be explained by the values of the self-induction and resistance of the armature.

2. The shape of the periodic curves depends on the character of the external circuit, and on the nature of the carbons and

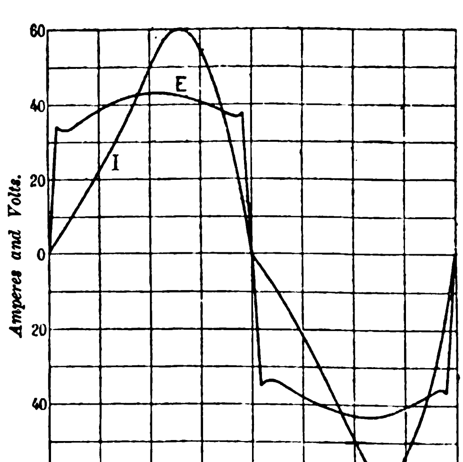

Fig. 8.—Cored carbons, high voltage, inductive circuit. l=4mm R=0·55ω, L=0·0066h, ϵ=94v, E=37v, I=37a, η=0·88.

of the cores. The extinction of the arc which takes place at each alternation is not always accompanied by a cessation of the current. This stoppage of the current becomes less marked as the circuit is made more inductive, and the core

Digitized by Google

more conducting. It is most marked when the arc is hissing, and the external circuit is non-inductive.

3. To interpret the results, it is necessary not only to consider the vaporisation of the carbon, but also the effects of the molecular bombardment, and the conducting power of the hot gases. There does not seem to be in the arc any back electromotive force in the true sense of the word.

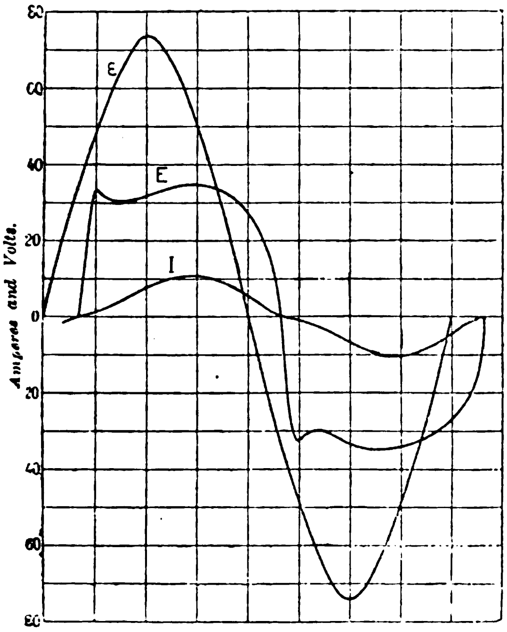

FIG. 9.—Cored carbons, moderate voltage, inductive circuit. $l=3$mm., $R=0{\cdot}10\,\omega$, $L=0{\cdot}016h$, $e=51{\cdot}5v$, $I=6{\cdot}8a$, $E=28{\cdot}8v$, $\eta=0.94$.

4. The power factor of the arc is very nearly unity for a silent arc and for soft carbons. With low-voltage arcs it may easily be 0·95, and the arc can then be treated as a non-inductive resistance. With uncored carbons, especially when the arc is noisy or hissing, the power factor can be as low as 0·70 when the frequency varies between 26 and 52 periods.

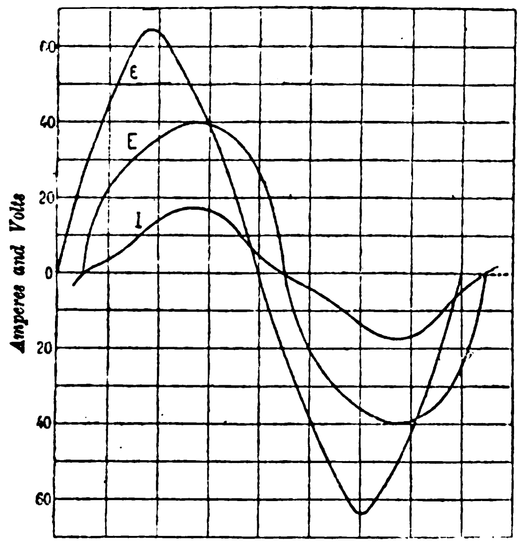

FIG. 10.—Cored carbons, moderate voltage, inductive circuit, $l=2{\cdot}5$mm., $R=0{\cdot}10\,\omega$, $L=0{\cdot}0048h$, $e=40{\cdot}5v$, $E=30{\cdot}6v$, $I=10{\cdot}9a$, $\eta=0{\cdot}97$.

5. The stability of the arc depends on the nature of the carbons, on the core, and on the electromotive force of the circuit (which must not be confused with the voltage on the carbons). It increases with the frequency, and is favoured by self-induction.

A Long Run.—The Westinghouse engine which drove some of the dynamos at Chicago ran 83 days 2 hours and 15 minutes without a break.

STANDARD SCREWS AND DRAW-PLATES.

The Société d'Encouragement pour l'Industrie Nationale has published a report by M. Gustave Richard on the question of the standardising of screws and draw-plates. This report, carefully examined and studied, will be found to possess great interest. The importance of the standardisation of wires has long been recognised by engineers and others, who have been struck by the inconvenience attending the diversity of our wire gauges. It has been proposed to adopt a uniform standard, in France by d'Armengaud, Denis Poulot, and others, in Germany by Rouleux, Delisle, and others. In England and the United States uniform systems have been adopted, which, in part, compensates for the absence of a decimal system. The systems adopted are those of Whitworth and of Sellers, and are constructed on the system of measurement of which the pound is the basis. In France the greatest disorder exists in this regard. The navy, the railway and maritime companies, the large manufacturing concerns, each and all have their special standard. The following are the chief characteristics of a unified system which has been drawn up by MM. Pierre, Redier, Bienaymé, and Sauvage:—(1) The shape of the gauge: an equilateral triangle, right truncated; this is a form easy of reproduction. (2) The sizes vary in half-millimetres. (3) A series of twenty numbered sizes forms a set, the gauges and diameters in which are determined by a formula of easy application. (4) Between the standard sizes thus determined all the useful intermediate diameters are intercalated.

The Société d'Encouragement pour l'Industrie Nationale proposes to convene a congress, at which this question shall be discussed by all who are interested in its issues, having for its object the final settlement of a definite system.

The British Association screw thread, which, according to the committee by whom it was introduced, was designed with special reference to Continental practice, seems to have been ignored. The only reason appears to be that it does not run in round numbers of millimetres. This is an absurd objection; for anyone who prefers to make his own taps and dies, and is really competent and equipped for the job, should be able to work to decimals of a millimetre as easily as to round numbers. But ninety-nine out of a hundred would not dream of "recovering" the gauge thus, and nine hundred and ninety-nine out of a thousand would buy working taps and dies, or at all events standards, from some reliable maker.

The British Association thread has taken firm hold in this country, and this is in no small measure due to the London Chamber of Commerce. We regret, however, that some very bad specimens of screws, said to be of the B.A. thread, have been turned out.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, December 15th.

ROYAL UNITED SERVICE INSTITUTION.

3 p.m. Lecture. "The Telephotos," by Col. G. E. Gouraud.

INSTITUTION OF CIVIL ENGINEERS.

7 30 p.m. Students' Meeting. The following Paper will be read: "Continuous Automatic Railway Brakes," by Mr. H. J. Orford.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting, at 28, Victoria-street. The following Paper will be read: "The Brightness of Light: its Nature and Measurement," by Messrs. T. M. Barr and C. E. S. Phillips.

TUESDAY, December 19th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. The following Paper will be read: "Hydraulic Power Supply in London," by Mr. E. B. Ellington, M.Inst.C.E.

WEDNESDAY, December 20th.

ROYAL METEOROLOGICAL SOCIETY.

8 p.m. Ordinary Meeting. The following Papers will be read: (1) "The Great Storm of November 16–20, 1893," by Charles Harding, F.R.Met.Soc. (2) "Rainfall and Evaporation Observations at the Bombay Waterworks," by S. Tomlinson, M.Inst.C.E., F.R.Met. Soc. (3) "On Changes in the Character of Certain Months," by A. E. THE ARC-STANDARD OF LIGHT.

The abstract of the Paper by M. ANDRÉ BLONDEL on "The Continuous-Current Arc as a Standard of Light," read before the Chicago Congress, is concluded in our present issue. The Paper was kindly abstracted for us by the author; the parts which have been omitted relate to matters which have been already published, and to suggestions presented to the Congress on the use of a secondary standard of light. To speak of a unit of light is to misuse the word unit as employed in physical science. Candle-power is the measure of the rate of emission of energy; not, however, of the total radiant energy of the source of light, but only of that part which can stimulate the human retina. Photographic electro-optical devices and radiometers may be employed, as Prof. ROSCOE and others have done, for certain physical researches; but the usefulness of the radiation as light must eventually be referred to the eye. The desideratum is a standard of light, and as the irregularities of atmospheric absorption put the light of the sun out of the question as a standard, we are driven to seek some artificial source of light. The Violle proposal and Siemens' modification of it exhibit a strong affection for, at all events, the C. of the C.G.S. system, in combination with the properties of a pure metal. Round numbers of centimetres are, however, of no use whatever in co-ordinating a standard candle power to any other physical quantities. The Hefner-Alteneck lamp can be constructed to the inventor's specification in millimetres, and used with the definite substance amyl-acetate; or the mean of a

large number of measurements of the British standard candle or of the French carcel lamp, or *bougie décimale*, under certain standard conditions may be taken. We need a convenient apparatus with which one of these standards can be readily reproduced, with the necessity, if possible, of but few corrections. The idea of screening an arc as METHVEN screened an Argand burner was very fascinating when it was first proposed, but the necessary apparatus for realising it turns out to be as complicated and expensive as that of the Violle platinum standard, and perhaps more difficult to manage. Another serious difficulty is the want of uniformity among carbons. The matter has been considerably advanced by M. BLONDEL, whose figures are now for the first time published; but, as he modestly admits, he has not yet produced a satisfactory standard of light.

Capt. ABNEY'S selection of the light from the positive carbon of an arc, as a qualitative standard of white light, is well known, but the screening or "diaphragmation," as M. BLONDEL calls it, seems to be a modern idea. Even if in M. BLONDEL'S hands the arc-standard had proved to be a thoroughly trustworthy standard, it is not likely that the priority or credit for discovery would have been seriously disputed. As our readers know, both Mr. SWINBURNE and Prof. S. P. THOMPSON had thrown out suggestions. Prof. S. P. THOMPSON has, we understand, made some experiments, and has published some calculations, while Mr. SWINBURNE, in collaboration with another investigator, had given some attention to the construction of a practical standard before M. BLONDEL'S first communication was published. Up to the present these investigations have not been thought ripe for publication, for, although they have proceeded on somewhat different lines to those of M. BLONDEL, they have approached no nearer to a satisfactory standard. While others have made suggestions, M. BLONDEL has not only carried out, but has published his work, and it is by publication, even of incomplete researches, that progress is made. The difficulty which has been experienced with the varying quality of carbons may prove less serious than M. BLONDEL thinks, but the expense of the apparatus, and other difficulties, such as the estimation of the area of the hole in the diaphragm, considerably impair the simplicity of the original idea. M. BLONDEL uses a hole of more than a millimetre diameter. Ordinary commercial photometry is now carried to within two per cent. error, and in the hands, or eyes, of some observers to one quarter or one-fifth per cent. A standard of light should therefore be accurately known, and reproduceable to within one-half per cent. This means that the diameter of the hole must be measured to within one quarter per cent., and that the hole should be truly circular. This is no easy matter. A way out of this difficulty may be to build up a square hole with straight edges and distance pieces, or as M. BLONDEL suggests, to use a lens of known absorption, as in the photometer of Dr. J. HOPKINSON, used in his lighthouse measurements in 1884.

The expense and trouble of an arc-standard, should it ultimately be improved and capable of three-figure accuracy, that is, involving an error of only a half per cent., need not prevent the establishment of such standards in national or other standardising laboratories, and by such standards secondary standards could be easily calibrated. For many purposes no better secondary standard can be employed than that to which Prof. AYRTON has given considerable care, in connection with the recent eclipse expedition, viz., a good glow lamp run at a low efficiency. The colour of the light is, at all events, not worse than that of an amyl-acetate flame, and, given a good ammeter, no corrections whatever are required. A secondary battery and a rheostat are needed, and to avoid the optical effect of irregularities of the glass bulb a diffusing screen must be employed.

M. BLONDEL'S Paper is a valuable contribution to photometric science, not only for the results of his work with the arc-standard and the modifications which experience has led him to introduce, but for the preliminary considerations on our present methods and standards. His assertion that "all methods of heterochromatic photometry are illusory" requires, perhaps, a little more explanation. The long and important work of Capt. ABNEY and Gen. FESTING can hardly be said to be illusory. They have established, with a completeness approached by no other investigators, the relations between different colour-sensations as perceived by the normal eye. It is only when candle-power is considered as a physical quantity that heterochromatic measurements become incommensurable. The object of electric lighting is not to cause a lamp to emit certain radiant undulations; but, as we have already suggested, to stimulate the optic nerves of the consumer who pays for it. He likes his wave-lengths in considerable variety and well mixed, but prefers them between 7×10^{-5}cm. and 4×10^{-5}cm., that is, light with as little heat as possible. One other statement in this Paper will not, perhaps, be accepted without further consideration, viz., "all measurements should be expressed in *bougie décimales*." The British standard candle is from 0·95 to 0·984 of a *bougie*, according to different observers. We have been informed that an attempt has been made during the last few years to reduce the value of the standard candle by altering the standard size of the Methven screen, but without success. The carcel lamp is, however, probably a much better standard than our candle; and as most scientific work is now referred to the amyl lamp, a change of 5 per cent. or so will affect nobody but gas companies, and a short Act of Parliament would soon settle them.

INSTITUTION OF ELECTRICAL ENGINEERS.

The following members constitute the Council of the Institution of Electrical Engineers for the year 1894. New members of Council or members occupying new offices on the Council have their names in italics:—

President.

Alexander Siemens, M. Inst. C.E.

Vice-Presidents.

R. E. Crompton, M. Inst. C.E.	Sir Henry Mance, C.I.E., M. Inst. C.E.
Sir David Salomons, Bart., M.A.	*Prof. George Forbes, F.R.SS. (L. & E.).*

Ordinary Members of Council.

Frank Bailey.	W. M. Mordey.
Prof. J. A. Fleming, M.A., D.Sc., F.R.S.	Prof. John Perry, D.Sc., F.R.S.
	James Swinburne.
Walter T. Goolden, M.A.	*Major A. H. Bagnold, R.E.*
Gisbert Kapp, M. Inst. C.E.	*W. B. Esson.*
Prof. A. B. W. Kennedy, F.R.S., M. Inst. C.E.	*Robert Kaye Gray.*
	Augustus Stroh.

Associate Members of Council.

G. K. B. Elphinstone.	*The Earl Russell.*
Dr. W. E. Sumpner.	

It was announced in the course of the reading of the annual report that the Institution Premium had been awarded to Mr. W. B. Sayers for his Paper "On the Prevention and Control of Sparking; Continuous-Current Dynamos without Winding on the Field-Magnets, and Constant-Pressure Dynamos without Series Winding." The Paris Electrical Exhibition Premium and the Fahie Premium were not awarded, but a Students' Premium was granted to Mr. W. R. Cooper for his Paper on "Primary Batteries."

MEMORIAL TO THE PRESIDENT AND COUNCIL OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

We have received a copy of the following memorial, addressed to the President and Council of the Institution of Electrical Engineers, which, we understand, is being largely and influentially signed :—

GENTLEMEN,—It will be within the recollection of the Council that in the year 1889 the composition of the Council, and their recommendations for the filling of the positions thereon then vacant, gave rise to so much dissatisfaction and complaint that a protest was addressed to the members of the Society and to the Council against the manner in which telegraph and telephone interests had come to be ignored in the composition of the Council. The discontent assumed such proportions that the Society stood in grave danger of a split, which, however, was happily averted by the frank manner in which the Council admitted the just claims of the telegraph and telephone professions to a fair amount of representation, and agreed to restore the balance at the first opportunity. Accordingly, at the next election, four representatives of these branches were recommended by the Council and duly elected. Year by year, however, as these particular representatives retired, the Council, instead of continuing the policy which they had admitted both directly and by their action to be just and reasonable, and proposing the election of other representatives from the same professions as the retiring members, did in no case follow that principle, but recommended the election of other gentlemen from professions already fully represented, until with the disappearance of the telephone representative in the present year the last trace of the successful agitation of 1889 has disappeared, and once more private and railway telegraphs and telephones are unrepresented except among the past and vice-presidents who, *ex officio*, are irremovable.

It is much to be regretted that the good understanding arrived at such a short time ago should have so quickly been upset, and that this question should once more have to be pressed on the attention of the Council by the private and railway telegraph and telephone members, who form so large a proportion of the institution. It is clear that the rules and regulations themselves are largely to blame for that lack of harmony and co-operation which are so essential to the well-being of any society. We, therefore, desire respectfully to lay before the Council and the members generally the following suggestions respecting the composition of the Council and the method of electing members thereof, begging that they may be considered merely as roughly indicating the lines upon which we consider alteration desirable.

(1st.) That the twelve ordinary members of Council should, as far as possible, consist of representatives of the following branches of the electrical profession, in something like the following proportions :—

3	members representing	Pure Science,
2	„ „	Electric Lighting,
2	„ „	Postal Telegraphs,
1	„ „	Railway Telegraphs,
1	„ „	Private Telegraphs,
1	„ „	Telephones,
2	„ „	Manufacturers.
12		

(2nd.) That when any of the representatives of any of the above branches retire the vacant seats shall be filled up by representatives from the same branches, so as to secure the permanent representation of the various branches in the fixed proportions agreed upon.

(3rd.) That it shall be competent for any twelve members, including proposer and seconder, to propose the election of a representative for the vacant seats, and on receipt of such nominations the names of the nominated person or persons shall be included in the balloting papers, such nomination papers to be in the hands of the Secretary not later than November 1st in each year.

We are of opinion that the adoption of the above suggestions will probably meet the difficulty, and give the members generally a more direct interest in the affairs of the Institution.

COMPENSATION FOR HYSTERESIS.

BY E. B. VIGNOLES.

The article by M. Abdank-Abakanowicz in the issue of *The Electrician* for Nov. 24th last is one which appears to call for some short comments from me, since a former note of mine on this subject has elicited from him the very interesting and lucid remarks in question. M. Abakanowicz begins his article by stating that he writes with the object of impressing the minds of the readers of *The Electrician* with some idea of the difference between his method and that of Mr. Evershed, to which I alluded; and I will therefore enter in further detail into the subject, in order to show that the difference is a superficial one, and depends merely on the point of view; in essence the methods are the same. M. Abdank-Abakanowicz has very kindly furnished us with a diagram, Fig. 1 (Fig. 4 of his Paper here reproduced), which will enable me to show clearly what I mean, aided by his accurate description of the principle of his instrument. In his "Results" 1, 2, 3, he states his principle of compensation to be this, that the force working his instrument is composed of two components, of which it is the algebraic sum; and these two components, if perfect compensation is attained, each go through, with rising and falling currents, a cycle, such that the difference of their ordinates remains constant for any particular value of current, whether rising or falling (and, we may add, whether positive or negative).

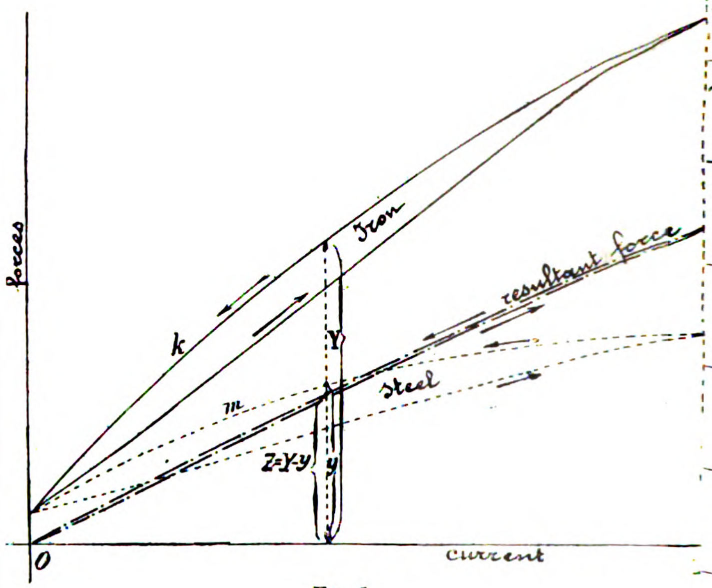

FIG. 1.

Now this is precisely what we did with the Evershed instrument in order to compensate it. The annexed Fig. 2 represents, in plan and elevation, the working parts of an Evershed movement. A A are the fixed blocks, B the attracted piece of soft iron, and C the compensating piece of steel. The force on the movement is the sum of two components, an *attraction* of the blocks A A on B, and a *repulsion* on B due to C, which forms a magnet of similar polarity. If these two forces go through the cycles "k" and "m" respectively (in M. Abakanowicz's Fig. 4), then perfect compensation will be attained. I think no further proof is required that the method of MM. Abakanowicz and Meylan is the same as ours; the only

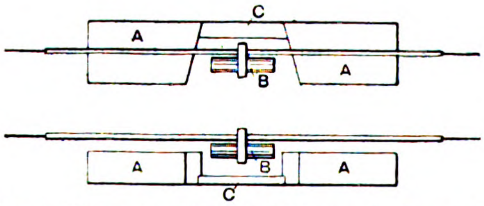

FIG. 2.—Plan and Elevation of Evershed Movements (Iron and Axle only shown).

difference lies in the application to a different class of instrument. It must be remembered that the object of our experiments was, as makers of commercial instruments (chiefly ammeters and voltmeters), to produce a type which while retaining the universally-used form of a moving system worked by alterations of magnetic resistance, should be devoid of hysteresis error, and I sincerely hope that if M. Abdank-Abakanowicz has hit on a method which produces this result as simply and more effectually than ours did, that he will communicate it, as promised, to the pages of *The Electrician*. It is easier to apply the method of compensation to the case of the wattmeter for

Digitized by Google

this reason, that in the wattmeter case only the induction cycles of the iron and steel need have the form shown, whereas in the ammeter and voltmeters the curves are complicated by the variation in force due to the variations in distance apart of the iron and steel parts of the movement.

I annex here a figure showing the percentage difference of reading of an ammeter compensated in this way on reversal of the current at various parts of the scale, compared with one not so compensated. The improvement is very marked; but in order to obtain more perfect compensation than this, an amount of adjustment is necessary for each instrument, which would be quite out of the question in commercial work. I may mention that this curve was shown by Mr. Evershed at the Institution of Civil Engineers, and a description of the method given, on the occasion of the discussion of Mr. Swinburne's Paper on "Measuring Instruments," in May, 1892. It is not improbable,

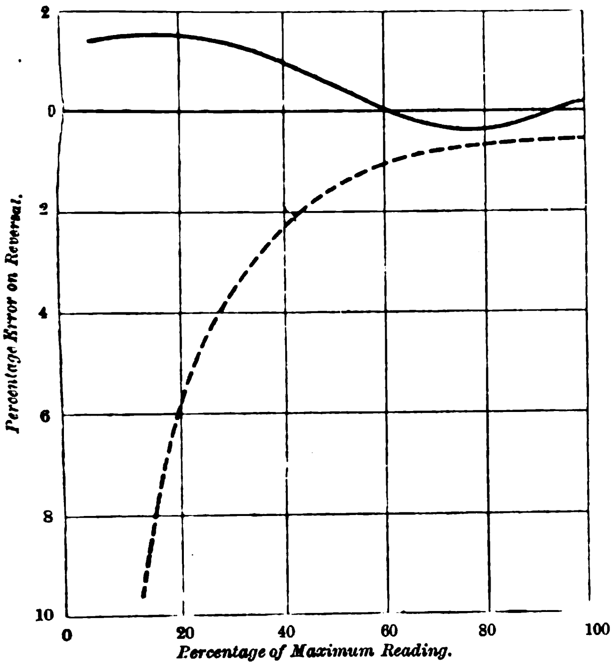

FIG. 3.—Full Line, Compensated. Dotted Line, Not Compensated.

since the subject has fallen into the hands of such able experimenters, that further progress has been made, and we shall look forward with great interest to the publication of MM. Abdank-Abakanowicz and Meylan's researches; but I think it must be acknowledged that to Mr. Evershed is due the credit of having been the pioneer in this field.

In conclusion, I may add that while I am sorry that the publication of this method in *La Lumière Electrique* and the *Elektrotechnische Zeitschrift* should have led me to discuss it prematurely, I regret it the less since my action has caused M. Abakanowicz to give us so interesting a summary of his work in connection with M. Meylan; and I rejoice that an investigation which the exigencies of trade prevented our pursuing should have fallen into such good hands.

THE HANSEN ARC LAMP.

The regulation of the arc in this lamp is effected by means of a pivoted electromagnet, which, on an increase in the resistance of the lamp circuit, is caused by a stationary armature to turn on its pivot to an extent corresponding to the increase of resistance, and thereby release the arresting mechanism which controls the movement of the carbons.

The chain-wheel around which the chain carrying the carbon-holders runs is mounted to oscillate with the electromagnet, but is so connected therewith that the point of its circumference where the chain carrying the upper carbon-holder runs off lies exactly in the axis of oscillation of the electromagnet, so that during the oscillatory regulating movement of the electromagnet with the chain-wheel the said point, and consequently the upper carbon suspended therefrom, will remain stationary, and only the opposite part of the chain carrying the lower carbon-holder will be moved according to requirement, so that the regulation of the arc will be effected by the movement of the lower carbon alone.

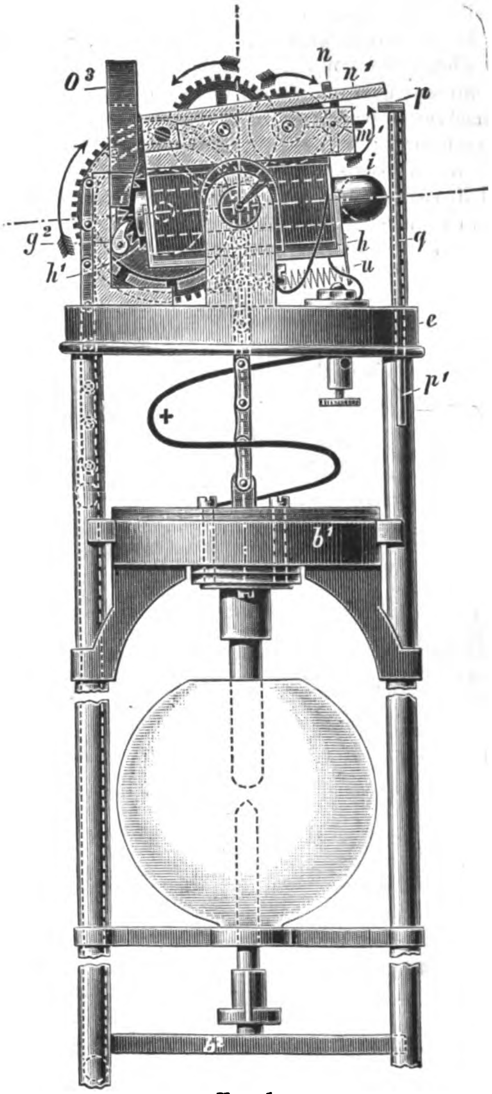

FIG. 1.

b^1 = top carbon-holder, b^2 = bottom carbon-holder, e = top plate, g^2 = detent, h = knife-edge, h^1 = knife-edge, i = pivoted electromagnet, m^1 = star wheel, n = pawl, n^1 = lever, o^3 = fixed armature, p = stop, q = rod, u = spring.

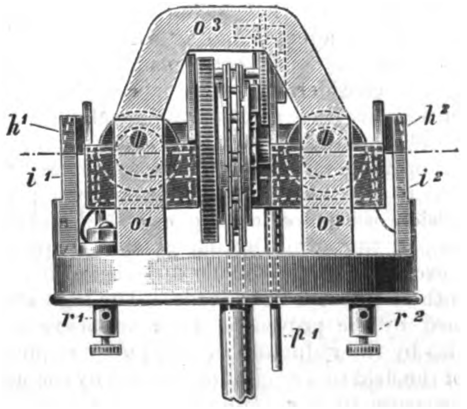

FIG. 2.

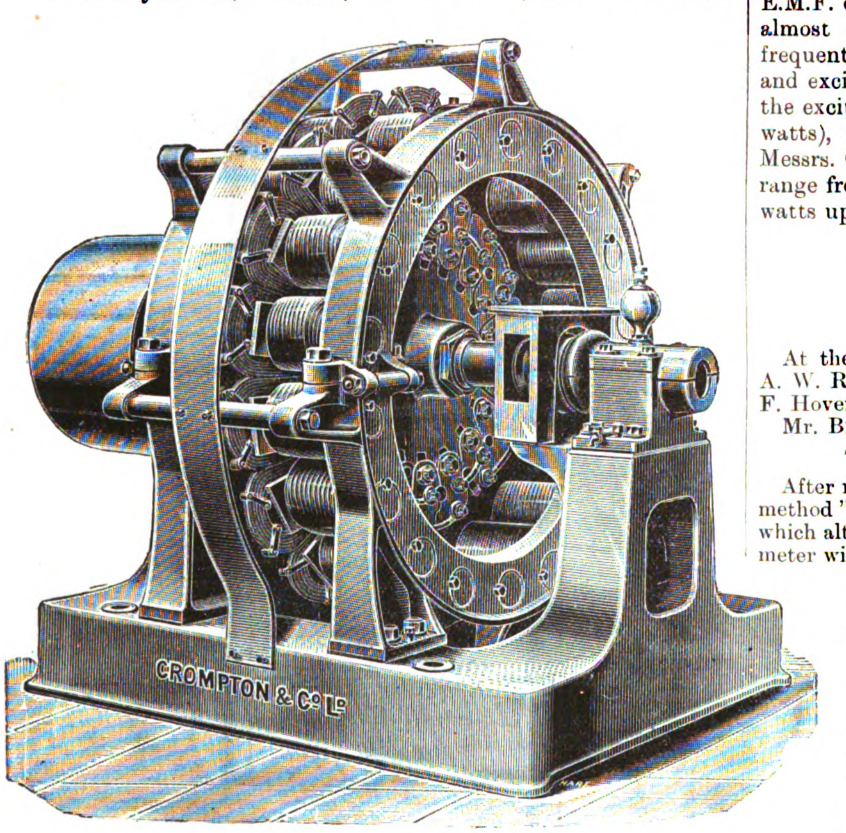
h^1 = knife edge, h^2 = knife edge, i^1 = lug, i^2 = lug, o^1 = supports, o^2 = supports, o^3 = fixed armature, r^1 = terminal, r^2 = terminal, p^1 = rod.

The regulating mechanism is mounted on the plate e, as shown in Fig. 2.

CROMPTON-BRUNTON ALTERNATOR.

Although Messrs. Crompton and Co.'s name has hitherto been chiefly known in connection with the supply of direct-current machinery, we understand that they have always had a full appreciation of the advantages of the high-pressure alternate-current system for all work where the distribution has to be carried out over widely-scattered districts where the lamp density is too low to pay for the larger amount of copper required for a direct system. They have, in carrying out contracts where the conditions warranted it, made use of the alternate-current system. They have, for some time past, occupied themselves in working out a complete system of alternate-current machinery; while, proceeding on well-tried lines, by a careful attention to proportions and mechanical details, they have succeeded in turning out designs which appear to be thoroughly reliable and extremely efficient. The most important item of such a system is, of course, the alternator, and we illustrate



above a 60 kilowatt machine. These alternators have revolving armatures and stationary field-magnets. The present is scarcely the place in which to detail at length the reasons which have led Messrs. Crompton and Co. to adopt this design in preference to that using a stationary armature and revolving field-magnets, and it will be sufficient to say that their choice has only been made after careful consideration and considerable experience with both types. Special attention has been paid in this machine to the following points:—(1) a ready access to the armature for inspection or repair by opening one or both upper halves of the field-magnets, which are hinged for that purpose; (2) facing; (3) the provision of a powerful magnetic field and small armature re-action, so that the alternators shall require but little variation of exciting current to suit variation of load; (4) high efficiency both at full and light loads. The high efficiency has been obtained by the provision of an armature without any iron core, also by the reduction of the power required for the excitation of the field to a minimum and also by the use of a light revolving armature giving a minimum of weight and loss of power at the bearings, and as a consequence, not the least important, a minimum of trouble. The armature is of the well-known disc pattern formed of sector-shaped coils fixed round a periphery of the hub. Probably the parent design of this type of armature is that described in Siemens' original specification of 1878; such an armature is, electrically, probably the best that could be devised, and it is only in the constructional details and proportions that improvements are to be looked for. The special features of the armature, as constructed by Messrs. Crompton and Co., are the methods adopted for attaching each armature coil to the centre disc, or hub, and the provision made for drawing it radially inwards toward the centre, so that the whole armature when mounted can be very securely tightened up, thus entirely preventing all detrimental vibration of the armature conductor, and making a very strong and rigid job. Moreover, a new armature coil can be quickly inserted at any time, and tightly drawn into place. The field-magnets, bearings, and other portions of the machine are of the usual type, and call for no description. The collector is entirely enclosed, to prevent all risk from accidental contact, and the brushes are in duplicate, so arranged that either may be removed for inspection when the machine is at work. The machine illustrated is designed to work at an E.M.F. of 2,000 volts at 600 revolutions, and it has been in almost daily use for the past eight months. It has been frequently run for experimental purposes (with increased speed and excitation) at over 3,500 volts. The power required for the excitation of the field at full load is only 1¼ per cent. (750 watts), and the commercial efficiency exceeds 91 per cent. Messrs. Crompton and Co.'s standard sizes of these alternators range from 15 kilowatts to 200 kilowatts, those from 65 kilowatts upwards being provided with three bearings.

PHYSICAL SOCIETY.

At the meeting of the Physical Society on Friday last, Prof. A. W. Rücker, President, in the chair, Messrs. J. H. Gillett and F. Hovenden were elected members of the Society.

Mr. Blakesley then read Mr. Swinburne's Paper on

"A Potentiometer for Alternating Currents."

After referring to the many advantages of the "potentiometer method" of measurement, the author describes an arrangement by which alternating pressures can be measured. A quadrant electrometer with a double fishtail-shaped needle suspended by a torsionless fibre is employed. The electrostatic attraction exerted by an alternating pressure between the needle and one pair of quadrants is balanced by the force due to a steady pressure between the needle and the other pair of quadrants. The magnitude of the steady pressure is determined by a potentiometer and standard cell, and the effective value of the alternating pressure thus deduced. For measuring alternating currents, a differential electro-dynamometer having two fixed coils and one moving coil, and no controlling spring, is used. A direct current, measured by the fall of potential over a small resistance, is passed through one of the fixed coils, the alternating current through the other fixed coil, and the moving coil is included in both alternating and direct current circuits. When the two forces balance the currents are taken as equal. Several small inaccuracies to which the method is subject are mentioned in the Paper.

DISCUSSION.

Prof. S. P. THOMPSON inquired if the fishtail-shaped needle of the electrometer was novel.

Mr. BLAKESLEY said the author had mentioned the needle previously. He (Mr. Blakesley) thought the name "Potentiometer" was not very suitable. In effect, the so-called measurement of *pressures* was a comparison of two *powers*.

The President announced that Mr. Preece's note on the "Specific Resistance of Sea Water" had been temporarily withdrawn, and Prof. G. M. Minchin made a communication on the

"Calculation of the Coefficient of Self-Induction of a Circular Current of Given Aperture and Cross Section."

Instead of assuming the cross-section of the wire small, and the current density constant over the section, as is usually done, the author takes into account the dimensions of the section and the non-uniform distribution of the current. Making use of the expressions for the vector potential (G) of the current given in his previous Papers (*Phil. Mag.*, April and August, 1893) the author calculates the total normal flux of force through a surface intersected once in the positive direction by every tube of force emanating from the given current. This flux divided by the current gives the coefficient of self-induction. The surface chosen is the circular aperture of the current, and the half of the anchor ring formed by the wire,

Digitized by Google

When the current density is inversely proportional to the distance from the axis of the circular current, the value for the coefficient of self-induction is found to be

$$\pi\left\{4a(L-2)+2c\left(L-\frac{5}{4}\right)-\frac{c^2}{16a}(2L+19)\right\},$$

where a is the radius of the central filament of the current, c the radius of the cross section of the wire, and $L=\log_e\frac{8a}{c}$. Clerk-Maxwell's approximate expression agrees with this in the principal term. As an example of the closeness of the approximation, the case of a current in a wire two millimetres diameter bent to a circle of 2 centimetres mean diameter had been taken, the approximate and corrected coefficients being 58·866, and 59·207 absolute units respectively. When the current in the wire is superficial, as in case of alternating currents of high frequency, the coefficient is somewhat greater, being given by the expression $\pi\left\{4a(L-2)+2c\left(L+\frac{3}{2}\right)+\frac{c^2}{16a}(4L+11)\right\}$. Incidentally it was pointed out that the function $G.x$ where G is the vector potential at a point distance x from the axis of a circular current was the same as Stoke's *current function* in hydrodynamics.

Prof. MINCHIN then read another paper on the

"Magnetic Field of a Current running in a Cylindrical Coil."

The cylindrical coil is regarded as a series of equal circles lying close together and forming a cylindrical surface. Replacing each circular current by its equivalent magnetic shell the problem of finding the magnetic potential at a point resolves itself into calculating the gravitational potential due to the circular plates of attracting matter, one positive and the other negative, situated respectively at opposite ends of the cylinder. The magnetic potential due to one plate is then deduced in terms of elliptic integrals of the first, second and third kinds. The President had pointed out that the expressions given in the printed proof of the paper only applied when the perpendicular from the point to the plate fell within the circle; the author had therefore modified the formula so as to be true generally. From this formula the equipotential curves can be constructed. The same system of curves serve for the plate at the other end of the cylinder by changing the signs of the numerals representing the potentials and giving the curves a motion of translation equal to the length of the cylinder in the direction of its axis. The equipotential curves for the coil can then be deduced by drawing through the points of intersection of the two sets of curves whose numerical values have a constant sum. In determining the curves, the author had to calculate tables of elliptic integrals of the third kind, and these he hoped to complete before the Paper was published. In reply to a question on the first Paper which had been brought before him by Prof. Perry, the author said that as the diameter of the wire diminished indefinitely, both the self-induction and resistance became infinite, but the ratio L/R became zero. It was interesting to examine what relation between the aperture and cross-section gave minimum impedance. If the ordinary expression for L be taken the problem was impossible, but the corrected form admitted of a solution.

DISCUSSION.

Prof. PERRY hoped the work Prof. Minchin had done so well for circles and cylinders would be extended to cylindrical coils of rectangular cross-section. It was most important to be able to find the shape of the field produced by such coils.

Prof. S. P. THOMPSON inquired if there was any way of deducing the expression for the magnetic force at a point other than that given in the Paper on the "Magnetic Field of Circular Currents" (*Phil. Mag.*, April, 1893).

In reply, Prof. MINCHIN explained how the formula followed at once from the fundamental theorem that magnetic force is the curl of the vector potential. This was based on Laplace's expression for the force between a magnetic pole and an element of current, which had been proved experimentally.

THE CONTINUOUS CURRENT ARC AS A STANDARD OF LIGHT.*

BY ANDRÉ BLONDEL.

(Concluded from page 147.)

Influence of the Core.

Here no doubt exists. It has been clearly shown by all experiments that the core added to the positive carbons plays an important part from the point of view of the brilliancy. This core consists generally of a mixture of powdered carbon and mineral substances, such as silica, silicate, &c., which give an artificial conductivity to the arc so that a certain current may flow without volatilising so much carbon as it otherwise would. The result is :—(i.) A reduction of the area of the surface brought to the maximum degree of incandescence ;* (ii.) a lowering of this maximum, as shown by the following tables, which are a summary of comparisons made either directly between carbons or between carbons and the carcel standard, the lights being very slightly different so as to render a comparison legitimate. The figures in the last column were obtained by directly comparing the intrinsic brilliancy of one of the carbons with the carcel standard. These figures are, therefore, all infected with the probable error of this comparison with a heterochromatic light.

Table IV.

It is the effect of the core which justifies the statement, frequently made by those who use the arc for projection work, that modern carbons have not as great an intrinsic brilliancy as those used in Foucault's days. The lowering of the intrinsic brilliancy is the greater the greater the conductivity of the core. The intrinsic brilliancy frequently goes down to 130 *bougies décimales* per square millimetre, and less in the case of low-voltage carbons, which require for an equal length of arc 35 volts in lieu of 45. Generally speaking the relative reduction of voltage caused by the use of the core gives a close approximation of the relative lowering of the intrinsic brilliancy.

Absolute Value of the Intrinsic Brilliancy.

None of the figures hitherto given by experimenters for the intrinsic brilliancy of the crater have been determined directly, and there is, therefore, no need for surprise at their being all far from the truth. The mean value of the emissive power deduced by me from more than 50 measurements carried out with homogeneous carbons of five different qualities is 158 *bougies décimales* per square millimetre, the figures varying from 152 to 163 *bougies décimales*. I think I may give as a practical figure 160 *bougies*

* Paper read before the International Electrical Congress at Chicago, August, 1893.

* Mr. Trotter has also drawn attention to the fact that the core usually appears darker than the rest of the crater. It is therefore pretty evident that the placing of the photometer at the corresponding part of the image must be avoided. In all my experiments I took care to keep the photometer in the part of the image where the carbon is homogeneous.

Digitized by Google

décimales, that is to say, more than double the figure (70 candles) recently given by Mr. Trotter,* and more than six times the figure (2·55 carcels) given by M. Allard,† which, truth to tell, could inspire no confidence. Voit,‡ at the Munich Exhibition, found 4·84 *bougies* per square millimetre; a figure still further from the truth.

It is noticeable how rapidly the intensity of the luminous radiations increase with the temperature, since the intrinsic brilliancy per square millimetre passes from 0·02 *bougies* in the case of platinum at 1,775°C (Violle standard) to 160 *bougies*—that is to say, 8,000 times more—for carbon at 3,500°C (the temperature found by M. Violle). The differences in intrinsic brilliancy observed in the cases of different kinds of carbon only correspond, therefore, to very small differences of temperature.

Phenomenon of the Hissing Arc.

As is known, under certain circumstances, the arc sets to work to hiss loudly, the voltage decreasing and the current increasing at the same time. No satisfactory explanation of this phenomenon has been given up to the present. It is most often attributed to impurities, or to a want of homogeneity in the carbons.§ By means of photographic analyses‖ I have been able to show directly that the hissing is always accompanied by jerkiness in the flow of the stream of carbon, which explains the shrill sound produced; whilst, on the other hand, a silent arc is accompanied by an absolutely uniform flow. I have observed, moreover, that the violet tint of the ordinary arc is replaced by a very characteristic blue-green tint, which seems to point to a lowering of the temperature. In the course of my experiments with the arc-standard I observed the two following additional facts of interest:—

(i.) At the moment when the arc begins to hiss, and the voltage suddenly falls,¶ the arc loses its transparency, and is transformed into an incandescent mist which hides the crater. When the hissing ceases, the arc suddenly becomes violet and transparent again, and the surface of the crater appears to be covered with black specks, which gradually disappear, and point to a lowering of the temperature of the incandescent surface.

(ii.) Whilst the hissing lasts, the intrinsic brilliancy is decidedly lower (10 to 20 per cent. at least) than it is during the normal silent state.

All these observed facts lead to the following conclusions, which seem to me to afford the true explanation of the phenomenon. The silent arc is one in which the transportation of the carbon takes place, owing to volatilisation at the surface of the positive crater. In the case of the hissing arc, on the other hand, the molecules of carbon are torn away by a disruptive discharge before being volatilised. They can, therefore, be carried across in greater numbers; the work done in this process of tearing away being less than that necessary for volatilisation, the temperature of the crater and of the arc and the fall of potential all decrease. The volatilisation theory and the disruptive discharge theory of Wiedemann** are in this wise reconciled. Hissing occurs whenever the current density becomes too great (0·5 ampere per square millimetre according to M. Luggin, 0·3 ampere per square millimetre according to my experiments). The disruptive tearing away takes place more easily when the carbons used are friable. This effect explains several phenomena observed in the case of the alternate-current arc; and it may also account for the slight difference previously mentioned which exists between soft and hard carbons by assuming that a very small portion of the carbon may be carried across disruptively even in the case of a silent arc.

Conclusions.

In conclusion, it seems to me that the law of the constancy of the intrinsic brilliancy is one of those theoretical laws accurate in their essential principles, but affected in practice by various secondary causes which it is difficult to eliminate. So long as we are concerned with mere commercial applications we may consider the intrinsic brilliancy as constant for all *homogeneous* carbons and to be about 160 *bougies décimales* per square millimetre. But for more accurate work, such as photometry, it must be admitted that, according to their origin, commercial carbons may exhibit appreciable differences. In order, therefore, to make use of the arc as a standard of light, it is necessary, until we are able to obtain pencils of pure carbon having a constant emissive power, to always employ the same kind of carbon and standardise it directly. The best for the apparatus I have described are hard, high-voltage, cored carbons giving a very steady light, the projected core appearing as luminous as the surrounding homogeneous portion. *Such a standard does not at present fulfil the necessary conditions for an absolute standard of light;* and it would not be a desirable one from several points of view. But, assuming a more modest position, it might form a *secondary standard* which would be very useful in the case of arc lamps, and would have a sufficient certainty. With the carbons I have just mentioned the relative error may be reduced to 2 per cent., a very low figure if we compare it with the light emitted by the lamps in question, and especially with the grave errors that arise from comparing arcs with a standard of different colour which does not enable us to measure the arcs in definite terms.

* Institution of Electrical Engineers, June, 1892. This difference, however, in no way affects the value of the noteworthy work of Mr. Trotter, who only referred as a matter of fact to the *average* brilliancy of the entire crater, which is always less than the maximum.

† M. Allard compared the arc to a luminous sphere of 1cm. diameter, a hypothesis which has no connection with the facts.

THE VERDIER ACCUMULATOR.

In a diminutive central lighting station recently started at Dieppe trial is being made of the Verdier accumulator. The Verdier plate is arranged horizontally, and consists of a sort of tray divided into a number of compartments by a series of vertical partitions, between which the active material (shown shaded in the accompanying

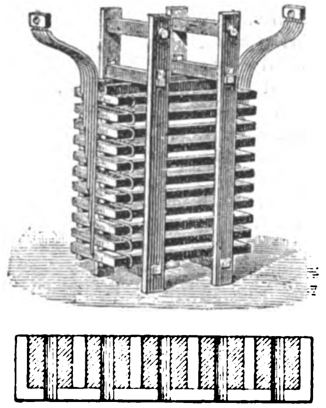

figure) is lodged. The plugs of active material and the bottom of the tray-like plate are perforated to permit of the circulation of the liquid and the liberation of the gases. The plates are placed one on the top of the other, and secured by an elastic frame.

LEGAL INTELLIGENCE.

The Medical Battery Company.

C. B. Harness, Managing Director of the Medical Battery Company (Limited), J. M. M'Cully, C. B. Hollier, and Dudley Towers, again surrendered before Mr. Hannay at Marlborough-street Police Court, on Wednesday, to answer the charges of having conspired together to obtain money by false pretences from divers persons with intent to defraud.

ARNOLD JACOB MARKS, managing clerk to Messrs. Morris and Co., one of the firms of solicitors prosecuting in the case, said that in his capacity as managing clerk he had the conduct of the action in which the Medical Battery were concerned. The one action was brought against the proprietors of *Science Siftings* for libel. The action was settled by a cheque purporting to be signed by Harness and one Smith. The cheque was for £1,300, and was given on April 29th last. On May 1st Mr. Harness and Mr. Fleet called upon him, and the former asked for the names of the people who had instructed Messrs. Morris and Co. to recover small amounts in respect of goods that had been sold by the Medical Battery Company, in order that he might return the amounts. A general conversation took place about the electrical appliances. Mr. Harness declined to join in a technical discussion, saying, "I have never bothered my head about the elementary parts of electricity. I took it up at the fag end." At one part of the interview Harness said to Mr. Hayman, "Now the matter is over I hope you will not further mention it in your paper. You have had your say, and the thing is settled." Mr. Hayman replied that he could not give him any such assurance. Mr. Fleet then asked that the compromise should not be mentioned in the paper, which request was also refused. Messrs. Woolf and Hayman left, and just as Mr. Harness was about to leave he said that he had plenty of business, and as Mr. Fleet was sick of his legal business he would give Messrs. Morris some of it.

Cross-examined by Mr. AVORY: Mr. Harness said he would give Messrs. Morris and Co. some of his legal business, but he had not done so. In certain cases where the people were poor Messrs. Morris gave their services for nothing in taking up the prosecution. The case of Mrs. Willcocks was taken up for nothing. Mr. Woolf, Mr. Hayman, and others were the proprietors of *Science Siftings*. He thought the circulation of *Science Siftings* had been increased by the action it had taken in the matter. About the middle of October he was in communication with the *Pall Mall Gazette*. A very small portion of the material supplied to that

Digitized by Google

journal was from him, and what he did supply was on the instructions of Mr. Hayman.

JOHN BELL, a linen factor, of Bow-lane, City, said that he was 82 years of age. In April, 1893, and for some time previously, he was suffering from hernia. On April 24th he went to 52, Oxford street, owing to the advertisements he had seen, with the object of getting a belt. He was ill for five weeks, and in bed all the time, owing to the treatment he received at Oxford-street. He brought an action subsequently against the Medical Battery Company, which was stayed. He did not purchase a belt from the Company.

Cross-examined by Mr. AVORY: The action was stayed owing to the liquidation of the Company. In the action he claimed damages for the injuries he received at Oxford-street. He might have suffered slightly from hernia for a year or two. Before he went to Oxford-street he had, under surgical advice, purchased a steel belt, which was of no use to him, and he was obliged to discard it. When he used the word "belt" he meant "truss," and it was to buy a truss that he went to Oxford-street.

M'CULLY said that he should like to make a statement, which was that as nothing material had been given in evidence against him he either should be discharged or, at all events, liberated on his entering into his own recognizances.

Mr. HANNAY: Is there any more evidence against M'Cully?

Mr. TERRELL: I have about 400 more witnesses to call.

The proceedings were adjourned till next Wednesday, the same bail being allowed for the defendants.

Under the winding-up order recently made against this Company the first meeting of creditors was held on Friday last at the Holborn Restaurant, London, W.C., under the presidency of Mr. Warley, Assistant Official Receiver. Proofs have been lodged for nearly £16,000. The Official Receiver's statement shows unsecured creditors £15,767, with Preferential claims, £106; and loans on Debentures, £8,150, the total liability to rank reaching £19,781. The assets include cash £592, the stock-in-trade is expected to produce about £500, other items being machinery, estimated to produce £1,000; fixtures, &c., £1,000; leasehold premises, £1,000; book debts, £48, and doubtful debts, £100. The Official Receiver states that the most important duties of a secretarial nature were performed by Miss A. Smith, who was nominally book-keeper and chief cashier. The Solicitor of the Company was a Mr. A. Fleet. Branch offices had been opened in Liverpool and Leeds, and very large sums had been expended in advertising. The receipts increased from year to year considerably until the beginning of 1893, when the articles in the Press, calling attention to the quackery associated with the business, seriously affected the Company's takings. Money being required it was resolved, in March last, to issue Debentures for £10,000, but the response from shareholders was unsatisfactory, and finally a scheme for increasing the capital of the Company to £200,000 by the issue of 20,000 Preference shares of £5 each was attempted. This, however, proved too much, and enabled a prominent journal to expose the quackery of the electric belts in a manner comprehendable by the general public. The money received on application for these Preference shares was returned, and the prospectus withdrawn. On November 3rd it was decided to wind up the Company. The salary of £1,000 per annum to Mr. Harness was increased in January, 1891, to £2,000 per annum, £4,500 was paid in dividends, and £10,000 during each of the three following years, while the Directors' fees during the same period amounted to £1,650. The largest shareholders in the Company were Mrs. Harness, £38,205; Mr. Harness, £7,225; Major Elers, £14,205; Mrs. Elers, £5,250; and Mr. M'Rae, £5,000. The accounts show a gross profit during the Company's existence of £274 260, and a present deficiency of £119,760. £15,862 was spent in advertising in 1889, £26,610 in 1890, £42,074 in 1891, £49,797 in 1892, and £36,535 in 1893, including contracts in hand up to the period when a receiver was appointed. Mr. Harness, who was present at the meeting, justified the large amounts taken by himself in various ways, and stated that the Company had been hounded down by the *Electrical Review*, the *Pall Mall Gazette*, and other papers. He regretted that the various libel cases had not been taken to the Court of Appeal, and expressed his intention to fight the matter out to the bitter end. Ultimately a resolution for the appointment of the Official Receiver as liquidator was put to the meeting, and carried unanimously.

At a subsequent meeting of shareholders, a committee of inspection was appointed, to consist of four creditors and three shareholders, in addition to Mr. C. B. Harness, Major Elers (another Director), and Mr. Fleet, who were selected to act on the committee of inspection in the interests of the shareholders.

The list of creditors in the winding-up of the Medical Battery Company is remarkable as containing the names of nearly every prominent journal throughout the country; and as evidence of the huge amounts of money spent in advertising the Harness belts, the *Illustrated London News* proprietors are creditors for nearly £480, and *The Sketch* (belonging to the same interest), £118. Items of £140, £360, £170, and similar large amounts, are sprinkled freely through the long list, which must in the aggregate represent an immense sum.

Strick v. Latimer Clark, Muirhead, and Co. (Limited).

This was a claim for commission, heard before Mr. Justice Wills on Tuesday.

According to the plaintiff's case the defendants requested him in 1889 to introduce them to certain persons who were about to acquire Parliamentary powers for establishing a system of electric lighting in certain areas of the city of Westminster, and the defendants promised the plaintiff that if he obtained for them the introduction, and if, in consequence, the defendants secured a contract or did business with the persons mentioned, the defendants would pay the plaintiff a commission. In February or March, 1889, the plaintiff introduced the defendants to Mr. Browne Martin, the Chairman of the Westminster Electric Supply Corporation, and that introduction resulted in a contract on December 5, 1889, by which the Corporation agreed to do certain work for not less than £100,000. The plaintiff claimed £1,000 commission. The defendants denied there was an introduction by the plaintiff, and, further, that if any commission was due the amount claimed was excessive, as the contract of December 5th was not definite, and, in fact, an action had been brought on it, and, after being heard for two days before Mr. Justice Hawkins and a special jury in May, 1891, a settlement had been arrived at, by which the defendants accepted £4,000 in satisfaction of all claims and costs. The defendants further contended that they had always been ready to give some gratuity to the plaintiff for obtaining the signature of Mr. Browne Martin to a document, and they paid £40 into court in satisfaction of all claims.

After hearing the evidence, and reading the correspondence between the parties, Mr. Justice WILLS gave judgment, and said that in cases of this kind, where there was a conflict of testimony about conversations, there could be no better way of getting at what actually took place than by looking at the correspondence. Here the plaintiff had claimed commission from the first. It was remarkable that if the Board, composed of the defendants, had always taken the view that no commission was due, and £40 was to be the only remuneration, nothing appeared to that effect on the correspondence. He thought the plaintiff was entitled to a commission as the introducer of a gentleman with whom the defendants afterwards did business. The only question was how much. It was understood that the amount was to depend on the business ultimately obtained. There was no principle on which the amount of commission in this case could be calculated, but, having regard to the settlement of the action before Mr. Justice Hawkins for £4,000, he thought £300 would be a proper amount to allow the plaintiff.

Judgment accordingly for the plaintiff for £260 beyond the £40 paid into Court.

Royce v. Feller.

In the Hull County Court Messrs. F. H. Royce and Co. sued Mr. Feller, proprietor of the Imperial Hotel, Hull, to recover £27. 8s. 8d. for electric-lighting work done and completed. It was stated for the plaintiffs that the work done amounted to £430, upon which the plaintiffs were willing to allow a discount of 5 per cent. for cash. Defendant did not acknowledge receipt of account until July 11th, when he sent a letter to the plaintiffs, in which he stated that he did not consider them entitled to charge for the switches for 22 extra lamps put in. Each lamp necessitated a switch, but he certainly never ordered switches. This appeared to be the only item in the account objected to by the defendant. He (defendant) had sent a cheque for the amount of the account, less the items for the extra switches supplied. Just before the action was brought on the defendant lodged a counterclaim against the plaintiffs, which Judge Bedwell, before whom the case was tried, declined to admit. After hearing evidence, judgment was deferred.

Liability for Injuries.

The case of Howard *v.* the London Electric Supply Company came before Judge Lumley Smith, Q.C., and a jury, in the Westminster County Court, on Wednesday, and was a claim for £50 damages for injuries alleged to have been received through the negligence of the defendants while laying mains in Rose-court, Dockhead.

Plaintiff's case was that she had to cross a trench, and trod on a stone which she thought was put for a bridge, and that toppled over, and she was precipitated into the trench, which had prevented her working since as a kitchen-maid, at 8s. a week and board, and it was quite probable that an operation would have to be performed, although the accident occurred as far back as the beginning of October. The defendants said all due care was taken to prevent accidents, and that plaintiff was at a place where there was no trench, and that she was more or less the worse for drink.

The jury found for the plaintiff for £20, and judgment was given accordingly, with costs.

CORRESPONDENCE.

VACUUM TUBE AND SECONDARY BATTERY EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I desire to add a few words to my letter in your last issue. Since that communication was written I have succeeded, by means of a simple device, to produce in a vacuum tube any predetermined number of bright and dark discs.

I may take this opportunity of correcting one word in the letter you printed. The word "dissociation" should have been "discation."

I will now venture to turn to another matter which is of considerable importance to the owners of secondary batteries.

It has hitherto been supposed that if the cells are left at rest for a long period, or if completely discharged, the positive plates are ruined.

Digitized by Google

In my little book on accumulators I studiously avoided referring to this question, having some doubts as to whether this was the case, and it is curious to notice that no one of my numerous correspondents has mooted this subject. To satisfy myself, I entered upon a long experiment, only ended a few days ago. Some cells were slowly discharged four years ago, and put on a shelf. The plates are now as good as ever, excepting that their colour is bad. As I anticipated, there is no loss of paste or buckling. I am now assured that if the exhaustion of the plates is not effected too rapidly, no harm is done by letting them stand for years. The next point is how to charge them up again? The plates are certain to buckle if charging is resorted to in the ordinary way. This point I have proved. A simple and certain way of proceeding, without injury to the plates, is to brush all the positives over with a stiff brush, or rubbed over with a slip of wood, without disturbing the section, in order to remove the surface scale. After this process charging may be resorted to, slowly to begin with, and without fear.

The knowledge of these facts increases the usefulness of secondary cells, and removes the chief deterrent to their use in cases where they have to be idle for long periods.—

Yours, &c., David Salomons.

Broomhill, Tunbridge Wells,
December 9, 1893.

THE COMMUTATION OF ALTERNATE-CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of November 3rd you comment on M. Pollak's proposal for obtaining continuous currents, or rather direct intermittent currents from harmonic electromotive forces; and you point out, among other objections, the waste which must inevitably occur in using a transformer with saturated core. M. Pollak's object in flattening his curve, as I understand it, is to prevent the heavy maximum current

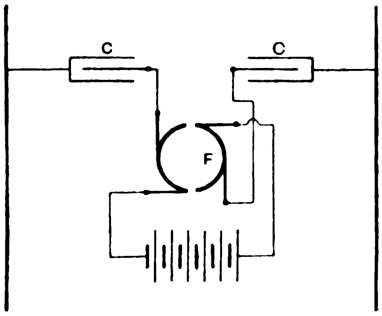

Fig. 1.

which would occur in charging accumulators from a harmonic electromotive force. I can see no other object in flattening the curve, because, for other purposes, an intermittent current would have the disadvantages of a fluctuating one.

The charging of accumulators is undoubtedly the principal end for which it is desired to re-dress an alternating current; and it appears to me that this might be done much more simply from the primary mains, with the aid of condensers. I believe that there is now no great difficulty in constructing condensers, to stand 1,000 volts or so, at moderate cost. The following is a method which should give satisfactory results. I may say at once that I have not had an opportunity of practically testing it, but some of your readers may think it worth while to do so. In Fig. 1, C C are two condensers, the outer coatings of which are connected to the primary mains, and the inner ones to two brushes on the commutator F, which for simplicity is shown as two-part. The other two brushes are connected to the terminals of the battery. The commutator is driven by a small synchronising motor. In Fig. 2 the curve A B C D E represents the voltage curve of the mains. This may be of almost any form which is likely to be met with in practice, but will probably not deviate much from a sine curve. Now, if the battery is cut out and the inner coatings of the condenser are joined together, the voltage curve will also represent the curve of charge in the condensers, and the current curve will be in exact quadrature with it, so that, neglecting small losses, no power will be expended in the system. When, however, the battery and commutator are in circuit, the charge curve will be displaced, vertically and will take the form A′ B′ B″ C′ D′ D″ E′ where B B′ represents the charging voltage of the cells, and B′ D′ are the points of commutation. The curve of current through the battery will now be O P Q. If the reversal takes place instantaneously, there will be at the point O a sudden discharge, probably of an oscillatory nature, from the battery, the total quantity of which will be equal to 2 v k, where v is the voltage of the battery and k the capacity of the condensers. The whole of this discharge is subsequently returned to the battery. I doubt whether this small quantity, however rapidly it may pass, would do any harm to the cells, inasmuch as it would hardly come from the plates at all, but from what may be called the polarisation at the surface. Be this as it may, there is no object in reversing instantaneously, and it would be better to provide an air-gap in the commutator, corresponding to O R (Fig. 2). The current curve will now be R S P Q, and there will be no discharge from the battery. The size of the air-gap need not be exactly correct. The capacity of the condensers will not be prohibitively large for moderately-sized cells. If the charging voltage is 100, and that of the mains 2,000, with a period of 100 ∾, then supposing the curve of electromotive force to be harmonic, the maximum will be about 2,900 volts. In calculating the effective charge the electromotive force of the battery must be deducted from this. The mean current (not mean square) will then be

$$C = 200 \times 2{,}800 \times k,$$

and

$$k = \frac{C}{560{,}000},$$

$$= 1{\cdot}8 \text{ microfarads per ampere.}$$

Each condenser must, therefore, have a capacity about 3·6 microfarads for each ampere of mean charging current, or 2·3 microfarads per ampere of maximum current. As

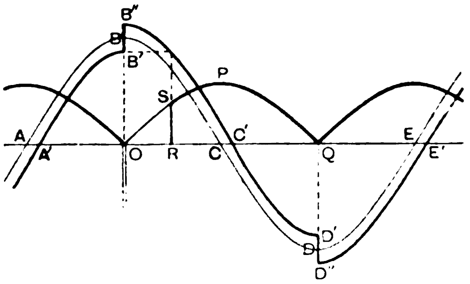

Fig. 2.

far as effect on the plates is concerned, it will probably be found to be correct to make the mean current equal to the usual charging current of the cells; but if the maximum is taken, then, of course, the charging must be carried on for a longer time.

The above-described method would have several advantages, the principal being that it would make little difference in the current whether one cell was being charged or a hundred cells. Theoretically, also, it would not affect the efficiency. Again, errors in setting the brushes on the commutator cannot produce violent currents likely to damage the cells. It is true that there would be some difficulty in measuring the current, but if the brushes are set at the sparkless position, the quantity of electricity passing through the cells can be calculated from the capacity of the condensers, care being taken, of course, that it is passing in the right direction. The large idle current may be urged as an objection, but it must be remembered that this is more or less in opposition to that of all the open-circuit or lightly-loaded transformers on the mains, and therefore little of it would come through the dynamo.

The leakage to earth, which is inevitable in all accumulators, would render it quite safe to handle the battery during charging, and the firework display at the cells, which would probably take place in the event of a condenser breaking

Digitized by Google

down, would give sufficient warning of such mishap. Some safety device might, however, be added to guard against this contingency.—Yours, &c., JOCELYN H. THOMSON.

18, Draycott-place, S.W.,
December 6, 1893.

HEDGEHOGS AND CONDENSERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Our attention has been drawn to your issue of the 3rd, in which you give an abstract of a Paper read before the American Institute of Electrical Engineers. At the conclusion of this abstract the authors are made to express the opinion that "the experiments with the condensers demonstrate the practicability of their use to diminish the line-current in transformer circuits, and point to their more extended use, as their manufacture is perfected and cheapened, not only in this, but also in other systems of alternating-current distribution." As the paragraph implies the non-existence of any practical condenser, we ask your permission to point out that we have ourselves been manufacturing condensers commercially (under the Swinburne patents) for the last two years, principally for Germany; and out of the total number supplied by us in this time only one has been returned broken down. We think, therefore, we are fairly justified in claiming to have solved the problem of condenser manufacture on a commercial scale, price being, of course, largely a matter of demand.

The Stanley Condensers used in these tests were made with waxed paper, a method discarded by us several years ago as quite useless for practical engineering work.—Yours, &c., SWINBURNE AND CO. (LTD.).

Broom Hall Works, Teddington, December 12, 1893.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

The 1893 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES DIRECTORY AND HANDBOOK" contains over 1,000 pages, several new and handy features having been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

The 1894 Edition is in preparation, and will be published in January next. New names, alterations of addresses, &c., should be sent in at once. The Directory blanks and circulars are not sent out until late in the year, in order that the most recent, and consequently the *correct*, addresses *only* shall appear in the book. Full printed particulars can be obtained, post free, from "The Publisher," *Electrician* Office.

TENDERS INVITED.—The Corporation of Harrogate invite tenders for the supply of concentric insulated cables for high-pressure distribution. Specifications may be obtained from Mr. Samuel Head, borough surveyor, and tenders, addressed to the Chairman of the Electric Lighting Committee, must be sent to the Town Clerk's office, on or before Saturday, the 30th inst. Further particulars appear in our advertisement columns.

TENDERS ACCEPTED.—The Newport (Mon.) Town Council have accepted the tender of Mr. W. Gradwell, Cardiff, for the erection of an electric lighting station, at £4,750. Fifty-two separate tenders have been received for the supply of electric light plant and apparatus, and these have been referred to Mr. R. Hammond, the Council's consulting engineer, for examination.

———— The Ealing Local Board have accepted the tender of Messrs. Wilkinson Bros., of Finsbury-park, London, N., for the erection of an engine and boiler house and accessories for £7,381. A tender for this work had been previously accepted, but the original contractor withdrew.

———— The contract for switchboards and connections for the Bolton Corporation's electric lighting scheme has been placed with the Manchester Edison-Swan Company (Limited), of Brasenose-street, Manchester.

———— The Dundee Police Commissioners have accepted the tender of Messrs. D. and G. Graham for the lighting of the Central Police Station at £107. 17s. 6d.

———— The tender of Messrs. W. H. Allen and Co. has been accepted for supplying electric lighting plant to the cruiser "Talbot," to be built at Devonport.

TENDERS RECEIVED.—The following tenders for plant in connection with the electric-lighting works have been received by the Halifax Town Council:—

	£	s.	d.
Pollitt and Wigzell, for two non-condensing steam engines (£1,480) and one small non-condensing engine (£380)	1,860	0	0
Yates and Thom, for three steel Lancashire boilers	1,688	0	0
Yates and Thom, for a Green's Fuel Economiser (£357) and brickwork for same (£132)	489	0	0
Electric Construction Company, for alternators (£1,785) and exciters (£270)	2,055	0	0
John Fowler and Co., for switchboard	460	0	0
C. A. Parsons and Co., for transformers	844	6	0
Siemens Bros. and Co., for supplying and laying underground cables, pipes, manholes, &c.	7,450	0	0
House service boxes	14s. each.		
Making house connections	15s. „		
Service cables	25s. „		
Watkins and Wilson, for excavating trenches: 1ft. 0in. deep	9½d. per yd.		
2ft. 6in. „	1s. 7d. „		

FOR SALE.—The Blackpool Corporation have for sale their arc-light plant, particulars of which are given in our advertisement columns.

PARTNERSHIP.—An old-established firm of manufacturing electrical engineers requires a partner. Some further particulars are given in our advertisement columns.

LIQUIDATIONS.—At meetings held at Taunton on the 9th and 24th of November, it was resolved that the Taunton Electric Lighting Company (Limited) be voluntarily wound up, and that Messrs. Albert Goodman and William James Villar, of Taunton, be the liquidators. It will be remembered that the Company's undertaking has recently been acquired by the Corporation of Taunton. Creditors must send in their claims on or before January 5, 1894.

———— The shareholders of the Aladdin Primary Electric Battery Company (Limited) have resolved to voluntarily wind up, and have appointed Mr. W. Hope, 5, Fenchurch-street, E.C., liquidator. A petition has been presented for the compulsory winding up of the Company (*see* last week's *Electrician*).

———— At a meeting of the shareholders of the Wenham Company (Limited), held at the offices, Upper Ogle-street, Fitzroy-square, on the 8th inst., it was resolved that the Company be wound up voluntarily, and that Mr. E. Cooper, 14, George-street, Mansion House, be the liquidator.

———— A petition has been presented for the compulsory winding up of Newington, Priddle and Co. (Limited), by Messrs. Bilbie, Hodson and Co., and is down for hearing at the Royal Courts of Justice, Strand, on December 20th.

———— The first meeting of creditors in Messrs. Woodhouse and Rawson United (Limited), under the winding-up order of May, 1893, is to be held at the Cannon-street Hotel, E.C., on the 21st inst., at 12 o'clock noon. Proofs must be lodged with Mr. C. J. Stewart, the official receiver and provisional liquidator, 33, Carey-street, Lincoln's Inn, London, W.C., not later than noon of the 19th inst. A statement of the Company's affairs has been lodged, and the summary will be forwarded to the creditors immediately.

———— Mr. Registrar Emden has directed separate meetings of (1) the debenture-holders and secured creditors, (2) the unsecured creditors, and (3) the shareholders of Elmore's French Patent Copper Depositing Company (Limited), to be summoned for the purpose of considering and, if thought fit, approving a scheme of arrangement proposed between the Company and its creditors. Such meetings will respectively be held on Wednesday, December 20, 1893, at 11 a.m. for the debenture-holders and secured creditors, at 12.15 p.m. for the unsecured creditors, and at 2.15 p.m. for the shareholders, at the Holborn Restaurant, London, W.C.

———— Creditors of J. R. Powditch and Co., Limited (in liquidation), must send in their claims to Mr. E. Hayes, the liquidator, 107, Cannon-street, E.C., on or before February 6, 1894.

BANKRUPTCY.—Amy Hall, trading as A. Hall and Company, electrical engineers, at South John-street, Liverpool, and Dolgelly, has executed a deed of assignment for the benefit of her creditors. The liabilities are given at £1,445, of which £120 are secured, and the net assets at £961. Among the creditors are Crompton and Company (Limited), £36; the Telegraph Manufacturing Company (Limited), £270; Wilson Hartnell, £99; Edison and Swan Company, £10; Woodhouse and Rawson United (Limited), £49; General Electric Company (Limited), £41; A. and R. Cochran, £18; G. Braulik, £20; Bayley Bros., £72.

AWARD.—Mr. H. T. Steward, who was appointed to arbitrate in the matter of the alleged injuries to the Monte Carlo Hotel, Leicester-street, London, W.C., by the electric-lighting engines used at the Empire Palace, and for which £2,000 damages were claimed by M. Guffanti, the claimant, has decided in favour of the Empire Palace Company on all points, M. Guffanti having to pay all costs.

REMOVAL.—Messrs. J. H. Tucker and Co. have, owing to the increased demand for their electric light fittings and accessories,

Digitized by Google

removed from Charles-road to larger premises at Ryland-street, Birmingham.

Messrs. Carrick and Ritchie.—This firm send us their recently-issued circulars relating to the Waverley turbine, in which particulars are given of water-power installations already completed. The circulars are illustrated, and can be obtained on application to the firm.

Electro-Magnetic Machinery.—The Thames Ironworks and Shipbuilding Company (Limited) have acquired the sole right of manufacture for the United Kingdom of Rowan's electro-magnetic, drilling, riveting and caulking machines, which have already met with favour amongst ship builders and bridge builders, owing to their portability and handiness, which give them advantage over hydraulic tools.

Calendars for 1894.—As usual, the close of the year brings a variety of sheet, pad, and book calendars, and one of the earliest to come to hand is a pad calendar issued by the Direct United States Cable Company, which, for general office purposes, will be found useful. Messrs. Street and Co., the well-known advertisement contractors, of 30, Cornhill, London, E.C., send us a framed and glazed sheet calendar of ornamental design.

Christmas and the Post Office.—A notice is issued calling particular attention to the fact that Christmas Day falls this year on a Monday, and that therefore it will be necessary for letters, book packets and parcels to be forwarded early, in order to reach their destination on Christmas morning.

Aberdare.—The Local Board are to discuss, at their first meeting in January, the question of lighting the town by electricity.

Alleged Forgery.—Henry Hunt, manager of the Taunton Electric Light Works, was again brought up before the Taunton magistrates to answer to the charge of having forged two promissory notes to the amount of over £276, with intent to defraud a coal merchant named Wyatt, who supplied coal to the electric light works. The local electric light company had duly paid for the coal supplied by Mr. Wyatt, but Hunt, instead of handing over the amount due, only made payments on account, giving the alleged forged promissory notes as security for the balance. Prisoner withheld his defence, and was committed for trial at the next assizes.

Ashover.—The Directors of the Ashover Hydropathic Establishment are debating the question of introducing the electric light into their establishment.

Blackpool.—Horses have taken the place of electricity on the Blackpool Tramways during the winter months, pending considerable alterations and improvements in the electrical equipments.

Bristol.—The Electrical Committee of the Town Council have presented their report on the Council's electric lighting scheme. It has been found that a balance is due to the contractors for the work done of £18,922. Extensions beyond the original contracts have been made in order to supply the light beyond the limits of the mains originally fixed. Considerable further demand is anticipated, which will necessitate the expenditure of £5,000 for additional plant, and an application is to be made to the Local Government Board for sanction to borrow £24,000.

Chatsworth.—The lighting of the famous Derbyshire seat of the Duke of Devonshire by electricity has called special attention to the value of electricity as a lighting agent for the ancestral homes of the great English families. Rooms at Chatsworth which were previously inaccessible to the public have now been opened, and the magnificent store of books and pictures may now be viewed.

Camberwell.—By a majority of 10 (32 against 22) the Camberwell Vestry have decided to postpone proceeding with the electric lighting question. The subject is to be prominently brought forward at the municipal elections in May next. It was estimated that an outlay of £50,000 will be required when the electric lighting scheme is proceeded with.

Church Lighting.—Messrs. J. S. Willway and Sons have installed the electric light in Broadmead Chapel, Bristol. This is the first place of worship in the district so lighted.——The Leamington Parish Church is to be lighted electrically at a cost not to exceed £260.——A proposal of the Gas Committee of the Aberdeen Town Council, for introducing the electric light into the city churches, was met by an amendment to the contrary, which was carried.——Greenhill Church, Derby, is to be lighted by electricity at a cost of £120.——The session of St. Paul's Episcopal Church, Edinburgh, are considering the advisability of introducing the electric light into the church.

Cork.—With regard to the City tramways, the Corporation have agreed to the proposal of the promoters, that the use of electricity or horse-power in the working of the tramways should be optional.

Decorative Electric Lighting.—Mrs. J. E. H. Gordon is contributing to the *Gentlewoman* a series of illustrated articles under the above title. The illustrations include several beautiful designs.

Devonport.—Messrs. Veale and Co., of St. Austell, Cornwall, have recently lighted by electricity the spacious premises in Tavistock-street, Devonport, occupied by the Wiltshire Bacon Curing Company.

Dover.—The seal of the Town Council was at the last meeting affixed to the transfer of the Provisional Order from the Council to the Dover Electric Light Company (Limited).

Dublin.—The report of the Electric Lighting Committee states that the excess of income over expenditure for the current year, and also for the year 1894, results in an estimated surplus up to December 31, 1894, of £1,129 odd, and that, therefore, no provision out of the rates will be necessary for the maintenance of this department for the coming year. About £3,000 increased expenditure is to be incurred, which is balanced by savings and estimated increased income. It is contemplated that a reduction will be made in the price to consumers. The report was adopted, Mr. Robinson stating that the electric light department promised to be the most profitable undertaking the Corporation possessed.——In the House of Commons, on Tuesday last, the Postmaster-General stated that no proposal was under consideration for lighting the General Post Office in Dublin, but that the new Parcel Sorting Offices in Amiens-street are to have the electric light.—In the House of Commons, on Monday, Sir John T. Hibbert stated, in answer to a question as to whether the Government were prepared to arrange for a system of electric lighting for the New National Library in Dublin, that the matter was under the consideration of the Board of Works and the library authorities.

Dumfermline.—The large works of Messrs. A. E. Walker Reid and Co. have recently been installed with the electric light by Messrs. J. H. Holmes and Co. The total number of lamps in the works is 1,500. Several other large works in the neighbourhood are being equipped for the electric light by Messrs. Holmes and Co.

Folkestone.—The Borough Association has forwarded a resolution to the Town Council, recommending that the electric lighting of the borough should be undertaken by the Corporation rather than by a local company. The Town Clerk has replied that the Corporation intend to keep the supply of electric current in their own hands.

Glasgow.—The long range of shops and buildings known as Argyle Arcade, at the back of Buchanan-street, Glasgow, have been purchased by Mr. S. Cranston, who intends to introduce the electric light throughout the buildings.

Grimsby.—The Council decided at their last meeting to approve the application for a Provisional Order for electric lighting. Many of the tradesmen of the town have promised to take the light, and the Mayor stated that doubtless, if they found it an advantage, they would be supplying it to the town before the expiration of two years, the period allowed by the Board of Trade for the completion of the works.

Guildford.—With regard to the proposed application of the Holloway Electricity Supply Company (Limited) for a Provisional Order for lighting Guildford by electricity, the matter has been referred to the General Purposes Committee, who will shortly present their report.

Hanley.—It has been decided to submit the plans and estimates for electric light and power to the Local Government Board for their approval, and to apply for sanction to borrow the necessary amount for the work required for the lighting and sewage schemes.

Harrogate.—At the last meeting of the Town Council a discussion arose as to the site for the plant of the electric light, and as to whether a refuse destructor should form part of the electric lighting plant and works. It was ultimately decided that a refuse destructor should be included.

Jedburgh.—Hartrigge House, the residence of Lord Stratheden and Campbell, is being fitted with the electric light, for which the current is generated by water power. A pond capable of holding 100,000 cubic feet of water has been made at the Tower Burn, and from this the water is taken along to the turbine, where there is a fall of 37ft., developing 20 H.P. The installation includes 140 lights for the house, 15 for the stables, and five for the laundry. An electric motor is employed in the stable yard for working chaff-cutting and other light machinery.

Lancaster.—The Market Place is be lighted by electricity, under the supervision of the Markets Management Committee. Satisfactory progress is being made with the electric lighting works.

Larne.—The Town Commissioners have had under consideration the tenders for lighting the town for the ensuing three years. The local Electric Light Company offer to light the town with eleven arc lamps of 1,200 c.p. at £11 per lamp per annum, six 32-c.p. incandescents at £4 per lamp per annum, and sixty-six 16-c.p. incandescents at £2 per lamp per annum, from dusk to midnight every day, except that no public lighting should be required for three

days before and two days after the full moon in each month. In the event of any failure the Company to forfeit a sum equal to the cost of lighting during the period of failure, at the price set out in the tender. The Company further state their opinion that the Commissioners would be well advised to purchase the installation, spreading the payment over a term of years. It was decided that the Board should come to a decisive understanding with the Electric Light Company as to price before deciding. The offer from the Gas Company was not entertained.

LONDONDERRY.—The Veterinary Department of Dublin Castle has sanctioned the use of the electric light by the Port and Harbour Commissioners for the inspection of cattle during the winter months, provided the installations consist of arc lamps erected to the specification of the Department. The work is, however, not to be proceeded with at present.

MELBOURNE.—The lighting of the City of Melbourne by electricity is expected to be complete by the beginning of the new year, and will cost between £70,000 and £80,000.

NEWPORT (MON.).—It has been decided to constitute an Electric Lighting Sub-Committee of the Town Council, consisting of Aldermen Davis, Moses and Huzzey, and Councillors Parnall, Jones and Pugesley. The Council have unanimously decided that a memorial should be presented to the Board of Trade, asking for a Provisional Order for lighting the borough by electricity.

PLYMOUTH.—A resolution that the Town Council apply to the Board of Trade for an electric lighting Provisional Order has been adopted. It will be remembered that the local gas company have applied to Parliament for powers for lighting the town by electricity.

RICHMOND MAIN SEWERAGE WORKS.—Messrs. Drake and Gorham have completed the electric lighting installation at Mortlake, and the trial run of twelve hours, with the whole of the plant and of the lights, was satisfactory.

SCARBOROUGH.—The Scarborough Electric Supply Company (Limited) notify that, in consequence of the success which has attended the introduction of the electric light, a reduced scale of charges has been fixed upon, to take effect from October 1st last. The new scale ranges from 6½d. per unit for supply of current not exceeding 200 units per quarter, to 5¾d. per unit for current supply exceeding 800 units. A reduction in the meter charge is also made.

SANTIAGO EXHIBITION, 1894.—Reference was made in our issue of November 24th to a forthcoming exhibition at Santiago. This is to be inaugurated in September and has the support of the Government. The object of the Exhibition is not to demonstrate the mining wealth of the country, but to collect in an international exhibition all the elements effectively contributing to the development of the mining industry, and more especially of metallurgy. It has been decided to make the conditions under which foreigners exhibit very favourable. Foreign firms desirous of participating must forward their applications to the Secretary of the Special Committee, which has been formed in Paris under the presidency of the Chilian Minister to France, 25, Rue Marbœuf, or to any of the Chilian Consuls. The Committee will defray the cost of sea and land transit of machinery and other objects exhibited, as well as the passage of workmen to instal and take charge of the exhibits. Motive power will be supplied free of charge to exhibitors.

THE "EXPLOSION" AT MANCHESTER.—The following is a sample of literary fare prepared for the readers of the *Somerset Express*. After referring to the accident at Manchester, of which a full account has appeared in *The Electrician*, the *Express* states that "about eight o'clock one morning pedestrians at the corner of Piccadilly, the heart of the city, were alarmed by a loud subterranean explosion. This was followed by the upheaval of a large stone trap-door, which closed the manhole of the electric-light wires. At the same instant a bright flame burst from the aperture, and mounted to a vast height. When it collapsed, and examination could be made, it was found that the cable was in a state of combustion. The electric supply had to be cut off before the fire could be extinguished. The people in Staplegrove-road are hardly so well situated as those in North-street for an affair of this kind, should it occur in Taunton."

SOUTHPORT.—Tenders are to be invited from the firms who tendered under the old specification for fresh tenders for high-tension mains under a new specification prepared by the Town Council's engineer.

STOKE.—Considerable improvements, extensions, and alterations are being made at the Stoke Railway Station belonging to the North Staffordshire Railway. Included in the improvements is the introduction of the electric light under the superintendence of Mr. J. Neale, the Company's telegraph superintendent, the work having been carried out by Mr. A. H. Lewis, under Mr. Neale's direction. Included in the installation is the North Stafford Hotel and several neighbouring buildings. The fittings have been supplied by the General Electric Company, of London and Manchester. The plant includes a 9½in. vertical high-speed engine by Messrs. Bumsted and Chandler, an Elwell-Parker dynamo, in addition to a 5½in. vertical Marshall engine, which drives a compound-wound Gülcher dynamo. The boiler and switchboard were made in the Railway Company's shops.

SWANSEA.—The question of the electric lighting of the borough is receiving the attention of the Corporation, who have called in an expert for consultation.

TAUNTON.—In consequence of the arrest of Mr. Hunt, as elsewhere reported, the Electric Lighting Committee of the Town Council have appointed Mr. W. H. Couzens as engineer-in-charge, *pro. tem.*

WALSALL.—As indicated in our last issue, the Town Council have discussed the special report presented in reference to the electric light and tramway schemes for the borough. The total amount of the tenders accepted for the work proposed to be done is £17,150. 10s., and the committee recommend that a further £2,500 be set aside as working capital, making the total outlay £19,650. 10s. The recommendations of the committee have been adopted. The Streets Committee also submitted a special report from Mr. F. Brown, the Corporation's electrical engineer, stating that the electric tramcar system had worked very satisfactorily, and that the line was in a good condition throughout. The number of passengers carried had increased from 1,871,816 in 1892 to 2,245,660 in 1893, and the public seemed thoroughly satisfied with the cars.

WEYBRIDGE.—Prof. A. B. W. Kennedy has presented his report to the Weybridge Electric Supply Company, which gives a description of the capacity and condition of the plant at the lighting station. The report is very favourable as to the condition of the machinery, &c., but Prof. Kennedy expresses his surprise at the very low price paid by the authorities for the public lighting, and recommends an early advance of not less than 50 per cent. If a local company is formed it will be necessary to expend about £16,000, from which an annual income is calculated at £1,755, which would leave a reasonable margin for profit.

WOLVERHAMPTON.—The Lighting Committee of the Town Council have presented their report, which states that, since the appointment of Mr. F. H. Lewis as electrical engineer to the Council, he had revised the original scheme of December 5, 1892, under which the tender of the Electric Construction Corporation was accepted at £28,772. 10s., subject to certain modifications, and the Committee have approved his recommendations, whereby the work, which was originally entrusted to the one firm, had now been subdivided. The scheme, as now approved, provides for a generating station at Commercial-road, from which the electrical energy will be transmitted to a central switch station at the Town Hall. From this central station the high-pressure current will be transmitted to various sub-stations in the compulsory area, which, to commence with, will be at the Art Gallery, Free Library, and Town Hall, where it will be transformed into low-pressure energy for distribution. The total of the tenders, plus the £1,320 estimated for arc lamps, &c., is £18,762. 14s. 2d., as against £28,762 in the original estimate. The total amount of capital expenditure for which a loan is sought will, therefore, be as follows:—Plant, as per tenders recommended, £17,442. 14s. 2d.; arc lamps, posts, &c., as estimated, £1,320; other capital items, as per list above, £4,020; add for estimated cost of buildings and for contingencies, £7,228. 5s. 10d.; total, £30,011. This shows a reduction of £10,000 as against the amount of the original tenders, which is partly due to the reduction of the plant to 5,000 lamps and partly to the economical revision of the scheme. The Committee recommend that the scheme be proceeded with, and that applications be made to the Local Government Board for a loan of £30,000.

YACHT LIGHTING.—Messrs. J. H. Holmes and Co., of Newcastle, have just completed the lighting throughout by electricity of Mr. Gordon Bennett's steam yacht "Namouna," the lights being arranged for decorative as well as useful purposes. A Belliss compound engine is used, coupled direct to a Castle dynamo, and the plant includes a battery of accumulators. The whole of the lighting of the yacht is by electricity. A number of novelties have been introduced, including the playing of a piano by means of an electric motor. The entire work is considered a great success.

19,423. VON DOLIVO-DOBROWOLSKY and Others. Electric-current distributing system.

19,534. DAVIS. Electric light switches.

COMPANIES' MEETINGS.

The General Electric Power and Traction Company (Limited).

The third general meeting of this Company was held at Winchester House, Old Broad-street, E.C., on Tuesday, the Right Hon. Lord Egerton of Tatton presiding.

The SECRETARY (Mr. Wm. Bulloch, C.A.), read the minutes of the last general meeting and the notice convening the present meeting,

The CHAIRMAN then said: Gentlemen, I regret to say that I have been asked to take the chair by the Board in the unavoidable absence of the Earl of Albemarle, who is prevented by serious indisposition from attending to-day. I am sure you will regret his enforced absence very much, as he is familiar with all the affairs of the Company. I have now to move the adoption of the report and balance-sheet. The Board have thought it well to call the shareholders together as soon as possible after the passing of the accounts and the closing of the books to the end of September, in order that they may be kept fully informed of the affairs of the Company, and the balance-sheet and profit and loss account be presented for the past year. I think they are drawn up in such a way as to show the position of the Company clearly and the result of the trading in the various departments. I am sorry to say that the general depression of trade still affects this Company, and that all the four businesses which in the first instance we thought there was a good prospect of developing, have not been as successful as we had hoped. With respect to the electric traction business, in consequence of the North Metropolitan Tramways Company not taking up the experiment which we had successfully instituted at Barking, and also owing to the general indisposition of municipal authorities to undertake any general system of electric traction, we have been unable to carry on that work at all; and at present, as you see from the balance-sheet, there is a depreciation, in consequence of the plant at Barking, which we are endeavouring now to dispose of, but which is at present unprofitable. In regard to the launches, there has been a slight profit during the past year, but it is not such as to induce us, I think, to go on and increase that branch very largely. There does not seem to be any very large demand for that class of business, and I think it would be wise if we could profitably dispose of that plant and concentrate our operations upon the manufacturing business and the copper-depositing business, to which I will allude further on. The profit and loss account is divided into two statements. Statement No. 1 deals with the result of the year's operations, which has, I think, been very clearly made out. Statement No. 2 shows the amounts which have had to be written off in the past year in respect of matters appertaining to previous years. You will see that on the manufacturing business there has been a profit in the past year of £1,010, and there has also been a small profit on the launch department, whereas in previous years there was a considerable loss. How-

Digitized by Google

ever, those two items of profit have not been sufficient to cover the standing charges and the maintenance of plant and launches, and there is a loss therefore in the general balance-sheet. On the other hand, we have very much diminished all the expenses of management. The management has been undertaken by the Electric Construction Company, who, as preference shareholders, are the most largely interested in this undertaking. You will also see by the balance-sheet that we have struck off all the Directors' fees, amounting to £862, which appeared in the last balance-sheet. That sum has been cancelled, and the Directors' fees have been reduced to the very lowest amount during the present year. With respect to statement No. 2, the £8,718 is not hard cash paid out, only two items of £572 and £1,318 representing money paid away—namely, the expenses connected with the upkeep of Barking, Windermere, and Manchester plants, including the sums paid for determining leases at Windermere and removing the Barking plant, and the expenditure and book items written off relating to liabilities incurred in former years, and settled or compromised this year. With respect to the manufacturing works, it was necessary, owing to the termination of the lease at Kentish Town, to come to some decision. There was an idea, which was mentioned in the last report, that the Kentish Town Works should be transferred to Millwall, where the copper-depositing process has been set up, but that would have been a very costly removal, and therefore we decided to recommend an amalgamation with the Acme Electric Works, that Company having good premises in close proximity to our Kentish Town works. Those premises are already equipped with suitable machinery for carrying on the manufacture of electrical apparatus, and the plant we have at Kentish Town will be transferred there. The premises are large enough to hold all the plant we have, and there will be comparatively little expense in the transfer, the premises being so near to our works. The Directors consider it desirable that this amalgamation should be effected by the formation of a new company, to be called the Acme and Immisch Electric Works, and it is proposed that the new works should be managed, as now, by the Electric Construction Company, in order to save the expense of a separate staff, and by that means a great deal of the subsidiary work which the Electric Construction Company perform will be carried out, and the works kept fully employed, at very much less cost than if there was a separate management. The terms of the amalgamation are based on the relative value of the two works, and this Company will receive five-eighths and the Acme Company three-eighths of the capital, which it is proposed should be £25,000, £20,000 being in fully-paid Ordinary shares, in the proportions I have just mentioned; and it will require an issue of £5,000 in Preference shares for the purpose of working capital. With reference to the copper-depositing works at Millwall, they have been finished, but the present state of the copper trade, which is in a very different position to what it was when the works were first begun, has rendered it a question how far it would be profitable to start them at the present time. We are waiting for a favourable opportunity, and are considering the question of providing the necessary capital for commencing operations there as soon as the market is in a favourable position for our doing so. With regard to the general position of the Company, it is quite evident that, under present circumstances, the capital of the Company is not fully represented by its assets, and that there is already a balance against it of £76,800. It is quite clear, therefore, that some reorganisation of the Company will have to be undertaken, and the deficiency of the capital account must be written off before any dividends are paid. At present the Preference shareholders would have the first claim on any profit that was made. The present time is certainly not favourable for starting any new commercial transaction, and therefore, although the general policy of the Board has been to try and reduce expenses, and to dispose, in the most favourable circumstances they can, of the existing works, which have been a source of loss hitherto, they are sensible that a general scheme of reconstruction must before long be carried out, and they are giving the matter their most earnest consideration. Whenever they see their way to submit any suitable proposal they will call the shareholders together and present it to them. I regret that I cannot give any more rosy description of the state of our affairs, but this is consequent on the general depression in all manufacturing concerns, owing to the financial difficulties of the past three years, but I think I have shown you that we have tried to reduce the expenses of the Company. Under the management of the Electric Construction Company we have introduced great economy, and have shown a profit in the launch and the manufacturing departments, and we are endeavouring if we possibly can to get some offer for the launch business. Nothing, however, has been brought before us which I can submit to the shareholders on this point, but the matter is receiving the earnest consideration of the Board.

Mr. MORITZ IMMISCH seconded the resolution.

In reply to several shareholders,

Mr. EMILE GARCKE stated that with regard to the management of the Company's affairs by the Electric Construction Company, it might be well if he explained what was the position at the last general meeting when the arrangement in question was entered into. At that time the Company had no manager, and the secretary had also resigned. The Electric Construction Company were very largely interested in this Company, and they had conferences with the Directors with a view to devising some scheme by which the management might be carried on more satisfactorily in the future. The result of these conferences was a suggestion that the management should be taken in hand by the Electric Construction Company. That simply meant that that Company should take up the position towards this Company which would ordinarily be held by a manager. There had been no other change. The Electric Construction Company simply attended to the details of the affairs of the Company. The Board met, as before, very regularly, and received a report from the manager of the Electric Construction Company, and the Directors determined on the policy of the Company, leaving it to the Electric Construction Company to carry out their instructions. The result of that policy had been that a very decided economy had been effected in the expenses. The Electric Construction Company received a fee for management, which included Secretary's services and the use of offices; and in referring to that point he might, perhaps, be allowed to explain that, although the volume of business done might appear to be small, judging from the results shown in the balance-sheet, it must be borne in mind that at one time the Company had a very large business from the point of view of the transactions it entered into. With reference to the manufacturing business carried on by the Company, the Company was established to carry on the business of Immisch and Co., which was doing a very satisfactory business in the making of motors and other electrical apparatus. That business had not been quite as satisfactory as it was formerly, and it had been their desire to work it up again; and he thought that the proposed amalgamation, which he hoped the shareholders would agree to that day, would have the effect of reviving the former credit of the previous firm of Immisch and Co. The profit shown in the first portion of statement No. 1 of the accounts had been made entirely on manufacturing and contracting; and this year, although the profit was not large, still it was stated in four figures. Information had been asked with respect to the position of the Ordinary shareholders in connection with the proposed amalgamation. The proposal was to form a new company, and to transfer their manufacturing business to that new company, receiving in consideration for the transfer fully paid up shares in the new company. It was the new company which would issue preference shares, and this company would be in precisely the same position as before, with this difference—that instead of holding the plant and machinery represented by their manufacturing business, they would hold shares in a company which would own those assets. The Preference shares referred to by the Chairman would be issued by the new company, and the shareholders of this company would be in precisely the same position as before. The profits would be divided in the proportion of five-eighths to this Company and three-eighths to the Acme Company. With regard to the management of the launches on the Thames, there had been mismanagement in the past, he thought, but it would be very difficult and altogether unprofitable at this stage to try and distribute the blame and to determine in what proportions it should be borne by parties who were not present. They had done much better on the Thames this year than in former years. He was not a Director of this Company, but he knew what great attention was being given to its affairs by the Board, and he assured the shareholders that the Directors were giving their very earnest attention to all the matters in question.

Mr. IMMISCH stated that he could add nothing to what had been said by Mr. Garcke regarding the manufacturing, but as far as the proposed amalgamation with the Kentish Town Works was concerned, he might say that he looked upon the scheme very hopefully.

The motion was then adopted.

Sir HENRY C. MANCE, C.I.E., afterwards proposed the re-election as Directors of Mr. Moritz Immisch and Mr. James Pender, which was approved, and Messrs. Ward and Wilding were re-elected auditors.

The CHAIRMAN then proposed the following resolution:—

"*That this meeting approves the agreement submitted to it, made between this Company and a trustee for the Acme and Immisch Electric Works (Limited), relating to the sale to the latter Company of the Kentish Town branch of this Company's business, and authorises the Directors to carry the same into effect subject to such modifications, if any, as they may determine.*"

After some discussion, this resolution was carried, and a vote of thanks to the Chairman concluded the proceedings.

The following is the report of the Directors referred to above:—

At the last annual meeting the shareholders were informed that arrangements had been made with the Electric Construction Company (Limited), by which that Company undertook the management of the affairs of this Company. The Directors have pleasure in stating that this arrangement has worked very satisfactorily, and the following comparative figures indicate the economies which have been effected in the management. The trading accounts for the past year show a profit on the manufacturing department of £1,010. 12s., and a profit on launch department of £31. 14s. 2d., whereas for the previous year the accounts showed losses of £3,121. 14s. 2d. and £570. 10s. 3d. respectively. Furthermore, the expenses of management, exclusive of Directors' fees, have been reduced from £3,727. 5s. 5d. in 1892 to £556. 17s. 2d. in the past year. The Directors have decided to cancel the amount of £862. 10s. standing to their credit at the end of September, 1892, and have debited the past year with only £186. 18s. in respect of remuneration. During the past year the Directors have determined sundry unprofitable transactions by sales and closing of leases, and have made provision for possible depreciation on such of the dismantled plant as is still unsold. The accounts, however, do not deal with the larger question, raised by the auditors in their report of January last, whether the book value of patents and goodwill should be further reduced. The Directors regard it desirable that the capital should be brought into conformity with the real position of affairs, and they are giving this matter their further consideration with a view to a re-organisation of the Company. The question of removing the manufacturing works referred to in the last report has received the anxious consideration of the Directors, and, with the assistance of the new management, they hope to overcome this difficulty in a way which offers many advantages over the original plan of removing the works to Millwall. An agreement has been made, subject to the approval of the shareholders, for an amalgamation with the Acme Electric Works at Kentish Town. This arrangement has the merit of providing suitable manufacturing works already equipped, at a smaller annual cost for rent and other standing charges than that at present incurred by the Company, and avoids the heavy cost of removing machinery to a distance, and the serious disorga-

Digitized by Google

nisation of the current business which this would involve. The copper-depositing works at Millwall are now completed, and the question of providing the necessary capital for commencing operations is receiving the consideration of the Directors.

Hove Electric Lighting Company (Limited).

The first annual general meeting of this Company took place in the Hove Town Hall on Tuesday last, Col. A. J. Filgate, R.E., presiding.

In proposing the adoption of the report (which appeared in our last issue) the CHAIRMAN pointed out that up to September 30th the Company had issued 3,290 shares, producing £16,450; that on that date they were in debt to their bankers to the extent of £2,500 on account of a loan guaranteed by the Directors, and that their other liabilities amounted to over £8,500, the bulk of which was due to the contractors. Against these liabilities they had the value of the actual work executed in the temporary and permanent generating stations, mains, plant, &c., £24,761; cost of meters, £583; office furniture, £69; and outlay on preliminary expenses and installation suspense account, £908. The revenue account up to September 30th showed a debit balance of £261. 10s., and considering the small demand during the early months of the Company's operations, that must be deemed satisfactory. On July 1st they had 52 houses connected with their system, representing 3,778 33-watt lamps; at the end of September the houses supplied had increased to 72, and the 33-watt lamps to 5,478, and at the present date they had 86 houses, and were supplying the equivalent of 6,225 33-watt lamps. Agreements had been signed for 14 additional houses, which would shortly be connected with their system, and from inquiries they had received they believed that number would soon be considerably increased. They understood that the Hove Commissioners were about to extend the light to the Town Hall, and they hoped the lighting of some portions of the town with arc lamps would soon be put in hand. On the whole there was every probability of the demand for the current being largely increased at an early date. But for the action of the contractors in carrying out the work of their contract largely in excess of the amounts for which the Company were able to pay they could not have attained that position. The capital needed for the construction of the first portion of the mains and the temporary generating station was, as they were aware, found by the Directors and their friends, and no appeal was made to the public for subscriptions until after the supply of electricity was commenced. The appeal then made did not produce the amount of capital they anticipated, nor did a second appeal made in the spring of the year. Being, however, fully satisfied with the progress made in the demand for electricity in Hove, and believing in the ultimate financial success of the undertaking, the Directors and Messrs. Crompton and Co. (the contractors) determined to do all in their power to push on with the work and fulfil the contract with the Commissioners. A main item in the contract was the erection of a permanent generating station, and as the demand for electricity was steadily increasing, it became apparent that, in addition to the contract obligation of the Company, the increased power provided by the permanent plant would soon be needed to meet the requirements of the public. Under those circumstances, the Directors obtained a temporary loan of £5,000 on their personal security to be devoted to the construction of the permanent generating station and electrical works, and the result was that those works were now approaching completion, and would, they hoped, soon be brought into use. In the meantime the demand for the electric current had so rapidly increased, while the days were also becoming shorter, that they were obliged to increase the temporary plant to ensure the demand being satisfied. The work the Company was doing in supplying electricity was largely in excess of what it was ever anticipated the temporary plant would be called upon to perform. Over six miles of mains had been laid, and more would have been put down but for a difficulty experienced in getting a sufficient supply of the casings which had to be used in the places where, owing to the position of the cellars, they were unable to construct concrete culverts. Their general policy in constructing mains was to tap the streets most likely to yield customers for the current—a policy which had been approved by the Commissioners, and one which they intended to adhere to as far as possible. From an approximate account of the working of the Company each week since July 1st he said that while in the earlier weeks the accounts showed a loss, that loss gradually diminished until near the end of September, when the returns commenced to show a profit, which had steadily increased since, and he thought it might be safely anticipated that the accounts for the half-year ending December 31st would show some profit after meeting all administration and other charges. Having devoted a considerable amount of time to looking into the affairs of the Company, he believed it was likely to prove a financial success. Their progress was distinctly more rapid than he had anticipated, and everything pointed to its continuing. Their undertaking was a local one, and so far as he could gather their reputation was good, and it was generally believed that the Company would be a remunerative investment, and they had no hesitation in recommending their enterprise to the people of Hove, and hoped they would soon supply the necessary capital to complete it. In regard to their future prospects in the deed transferring the Provisional Order to their Company, it was provided that no charge could be required from the Company in their schedule of charges during the first seven years of their existence. After that period the Hove Commissioners could only move the Board of Trade to reduce their scale of charges if the Company, in the seven years preceding, should have earned such a profit as would enable them to pay dividends at the rate of 10 per cent. per annum for the whole of such period. The Chairman concluded by expressing the satisfaction of the Directors with the excellent way in which the works had been carried out by Messrs. Crompton and Co. and their staff, and moved the adoption of the report and accounts.

Mr. CARLETON E. TUFNELL seconded the motion.

Mr. R. E. CROMPTON supported the motion as an old hand at electric lighting, and as engineer, first to the Hove Commissioners, and afterwards as head of the firm of contractors who carried out the work. He knew of no case where such good results had been obtained under such circumstances as at Hove. A large proportion of the inhabitants had shown appreciation of the light, and he considered the success of the Company had been reduced to a mathematical certainty. He joined in the appeal of the Chairman to the inhabitants to make the undertaking a local one. They wanted local support, and the money paid by the users of the light to be a source of income to the residents of Hove themselves. The security was, in these days, exceptionally safe, being not dependent on the fluctuations of trade like so many other incomes were. Speaking of the generating plant, Mr. Crompton said the design was the latest, and would work most economically. The works' cost had been reduced to a certain figure per unit, 3·3 lower than had ever been accomplished before for the same outlay. The more widely the results of the enterprise so far were ventilated the better for the Company, which wished to increase their capital to complete their works, and for the users of the light, because cheap manufacture meant cheap prices eventually.

Mr. WOODRUFF (Chairman of the Hove Commissioners) said that already they had realised a success far more than Mr. Crompton ever promised the Commissioners when he advised them as engineer. He (Mr. Woodruff) advocated the provision of a temporary station very strongly. The Company acted wisely in adopting his suggestion. When they looked at what had been accomplished by the initiatory work, he thought they were fully justified in anticipating a rapidly-increasing demand for the ight. He gathered that they expected to turn out the current at about threepence or less a unit, and he could see no reason whatever why the Company should not prove a very great financial success.

The motion was then carried unanimously, and a vote of thanks to the Chairman terminated the proceedings.

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, *pages 320-348, &c., &c.]*

ARTHUR H. BATEMAN (LIMITED).—This Company was registered on November 29th, with a capital of £5,000, in £1 shares, to carry on the business of emery-wheel makers, machinery manufacturers, iron and brass-founders, mechanical engineers, &c.

BILLING AND COMPANY (LIMITED).—This Company was registered in November, with a capital of £5,000, in £1 shares, to carry on the business of art-metal workers, brass founders, ironsmiths, gas, electric, ventilating, and general engineers, &c., at Smart's-buildings, High Holborn, London, W.C., and elsewhere.

R. AND. J. DEMPSTER (LIMITED).—This Company has been registered with a capital of £100,000, in £10 shares, to acquire the business of gas engineers and contractors hitherto carried on by R. and J. Dempster at the Gas Plant works, Newton Heath, Manchester, and to develop and extend the same.

ROSE, DOWNS AND THOMPSON (LIMITED).—This Company has been registered, with a capital of £50,000, in £10 shares, to acquire as a going concern the business now carried on under the style of Rose, Downs and Thompson; and to carry on the business of engineers, oil refiners, general merchants, &c.

UNIVERSAL ELECTRIC LIGHTING COMPANY (LIMITED).—This Company was registered on December 7th, with a capital of £5,000, in 10s. shares, to generate, produce, store, accumulate, and distribute electricity, electromotive force, or other similar agency, for the lighting of omnibuses, tramcars, cabs, and other vehicles, and for public and private buildings, manufactories, mines, ships, lighthouses, railways, &c., to acquire the right to use and put up telegraphs, telephones, electric bells, phonographs and all electric apparatus, including the formation of telephonic exchanges, to construct railways, tramways, or waterways, and to apply to the same, by means of central stations for generating electricity or otherwise, any means of electric locomotion, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of and dealers in electrical, telegraphic, telephonic and scientific apparatus. The subscribers (with one share each) are:—James F. Rogers, 108, Penton-place, Kennington, S.E.; C. F. Croll, 8, St. Agnes-place, Kennington-park, S.E.; H. Gibbs, 65, Glyn-road, Homerton, N.E.; G. F. Wenborn, Shipbourne, Tonbridge, Kent; W. J. Griffiths, 40, Albert-road, Stroud Green, N.; H. H. Clayson, 27, Borthwick-road, Stratford, S.E.; and R. B. Webster, 3, Kendal-villas, West Dulwich, S.E.

ELECTRO-ALKALI COMPANY (LIMITED).—The statutory return of this Company, made up to February 10th last, has been filed. The nominal capital is £160,000, divided into 10,000 Ordinary, 5,000 Preferred, and 1,000 Deferred shares of £10 each. All the Deferred shares have been subscribed for and allotted, and a call of £2 per share made. The calls paid amount to £734, and £1,266 is in arrears. The Electric Construction Company (Limited) hold 623 shares.

D. HULETT AND CO. (LIMITED).—The annual return of this Company, made up to October 2nd, has been filed. 5,900 Ordinary and 100 Founders'

Digitized by Google

shares of £5 each, out of a nominal capital of £35,000, have been subscribed for and allotted. Of these, 4,000 Ordinary and the Founders' shares were issued as fully paid, while the full amount has been called and paid on the remaining 1,900 Ordinary shares.

J. C. HOWELL (LIMITED).—The annual return of this Company, made up to November 13th, was recently filed. Out of a nominal capital of £25,000, in £5 shares, 2,907 shares have been taken up, of which 2,000 were issued as fully paid to John C. Howell, the vendor. Upon the remaining 907 shares the full amount has been called, resulting in the payment of £4,510, and leaving £25 in arrears.

ERNEST SCOTT AND MOUNTAIN (LIMITED).—The annual return of this Company, made up to October 23rd, has been filed. 5,663 shares of £10 each have been taken up, of which 2,200 have been issued as fully paid. Upon 972 shares the full amount has been called, upon 500 £5 per share, and on 1991 a call of £6. 5s. per share has been made. The calls paid amount to £24,412, leaving £251. 15s. as yet unpaid.

LINEFF ELECTRIC TRACTION AND LIGHTING SYNDICATE (LIMITED). The annual return of this Company, made up to November 27th, has been filed. The nominal capital is £15,000, in £1 shares, of which 11,431 have been taken up. Of these, 8,003 were issued as fully-paid, while £3,428 has been called and paid on the remaining shares.

MONTE VIDEO TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to November 14th, has been filed. The nominal capital is £220,000, divided into 29,000 Preference and 15,000 Ordinary shares of £5 each. All the Ordinary and 28,000 Preference shares have been taken up, and 3,000 of each description have been issued as fully paid. The remainder have had the full amount called, resulting in a total payment of £185,000.

ORME'S ELECTRIC SIGNAL SYNDICATE (LIMITED).—This Company has recently entered into an agreement with John Orme, of 65, Barbican, London, E.C., for the acquisition of British patent No. 20,742 (1891), and a provisional patent dated February 17, 1893, granted to the vendor in respect of an invention in relation to electrical and automatic signalling, and all improvements therein, and in consideration has agreed to allot 6,000 Ordinary shares as fully paid to the vendor. Messrs. Samuel Jennings and William M. Grimshaw have joined the Board of Directors.

CITY NOTES, &c.

ALUMINIUM COMPANY (LIMITED).—Mr. Justice Wright will, on December 20th, hear the petition for confirming a resolution passed by the Company reducing the capital from £400,000 to £80,000.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ending December 10th were £911, as against £933 for the corresponding period of last year, being a decrease of £22. The total receipts for the half-year amount to £19,132, as against £18,976 for the corresponding period of 1892, an increase of £156.

COMMERCIAL CABLE COMPANY.—This Company has decided to redeem on January 15th next the whole of their outstanding mortgage debentures, amounting to £80,000.

CONSOLIDATED ELECTRIC COMPANY.—This is the title adopted by the amalgamation of the St. John's Street Railway Company of St. John's, New Brunswick, the Eastern Electric Company, and the New Brunswick Electric Company, which have recently amalgamated.

DOVER ELECTRICITY SUPPLY COMPANY (LIMITED).—The prospectus of this Company invites applications for 7,000 Ordinary shares of £5 each, being part of a share capital of £50,000. The Company is formed to undertake the supply of electricity in the Municipal Borough of Dover under the Provisional Order granted to the Corporation and transferred to the Company, who, by the agreement with the Corporation, are empowered to supply current to the public lamps to be erected in the principal streets of the borough. The term of this contract for the public lighting is for 21 years from the date of the first supply of current, and the Corporation have the right to purchase the undertaking within six months after the expiration of a period of 21 years from the date of transfer, and again within six months after the expiration of a subsequent period of ten years upon payment to the Company of the value of the undertaking and goodwill as a going concern, with an allowance of 10 per cent. for compulsory purchase, the value to be determined, in case of difference, by arbitration. The maximum price per unit for current is fixed by the Provisional Order at 8d., and a sliding scale is provided under the agreement with the Corporation. The Brush Electrical Engineering Company have contracted with the Company for the supply of the necessary generating plant and apparatus, and for the laying of the necessary mains for current equal to 10,000 8-c.p. lamps and for 25 2,000-c.p. arcs. The subscription list opened on Monday last, and closes on Saturday at 4 p.m. Prospectuses can be obtained at the offices of the National Provincial Bank of Dover and London, or from the office of the Company, 49, Queen Victoria-street, E.C. The Board of Directors includes the Mayor of Dover. (Sir William Crundall), Mr. B. H. Van Tromp, and Mr. R. Percy Sellon, The engineer and manager is Mr. A. J. Lawson, and the secretary Mr. B. Broadhurst.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment on January 15th next of interest of 3s. per share, less income-tax, being at the rate of 6 per cent. per annum, on the Preference shares for the quarter ending December 31st, and the usual interim dividend of 2s. 6d. per share on the Ordinary shares, free of income-tax, in respect of profits for the quarter ended September 30th. The transfer books are to be closed from January 8th to 15th, both days inclusive.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company on Wednesday declared an interim dividend, for the quarter ended September 30th last, of 2s. 6d. per share, free of income tax, payable on the 16th proximo. The Share Register will be closed from the 8th to the 15th proximo, both days inclusive. The coupons on the Company's Five per Cent. Australian Government Subsidy Debentures, due on the 1st prox., will be paid on and after that date at Messrs. Barclay, Bevan and Co.'s Bank, 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—The numbers are published of 117 Six per Cent. Second Mortgage Debentures in this Company, which were drawn on the 8th inst. in accordance with the deed of trust dated August 16, 1893. The debentures are for payment at par on the 1st proximo.

ELMORE'S FRENCH COPPER DEPOSITING COMPANY (LIMITED).—Messrs. Maddisons, solicitors, point out that the 5,000 Founders' shares forming part of the purchase price of the French factory and patents have no face value, but are to receive £4,500 a year after the payment of 10 per cent. on the £80,000 new capital found. These Founders' shares are also entitled to half the surplus profits beyond such prior payments after a provision for reserve, as required by French law. It will be remembered that Mr. Duncan, who is receiver for the debenture holders, was asked to accept the office of liquidator, and expressed his willingness to do so as soon as the sale in France was actually completed. Messrs. Maddisons further state that they have already received the £8,600 in cash which forms part of the purchase price, and hope that before the 20th inst., when Mr. Duncan's appointment is to be confirmed, they will have received the obligations (£60,000) and Founders' shares.

EXPLORATION COMPANY (LIMITED).—The Directors of this Company have just issued their report to November 30, 1893. The Company are concerned in the promotion of the Central London Railway, and the report states that the formal approval of the City Commissioners of Sewers to the plans of the station and subways was obtained in June last, and that all necessary Parliamentary and other powers for the carrying out of the undertaking have been obtained, but that owing to the unfavourable state of the Money Market the issue of capital has been postponed. The report shows that the rumour that other than electrical power is to be used on the railway is unfounded.

GLOBE TELEGRAPH AND TRUST COMPANY.—The Directors of this Company have declared an interim dividend of 1s. 3d. per share, payable on the 18th proximo.

NIAGARA.—The *Financial News* states that a firm of real estate agents at Buffalo, New York, are issuing a circular calling attention to the utilisation of the Falls of Niagara for generating electrical motive power, and urging capitalists on this account to come in and purchase large plots of building land in the neighbourhood of the Falls, as "building land is very cheap in this territory, and as it will all be required for building purposes during the next five years it is reasonable to suppose that the values will go up by leaps and bounds." It is pointed out in the circular that a company consisting of the Vanderbilts and other multi-millionaires has been at work for some years, "and on or about March 1st next will be ready to supply 120,000 H P.," which will have the effect of revolutionising the value of real estate in the present small city of Niagara Falls and all along the twelve miles from Niagara to Buffalo.

PANULCILLO COPPER COMPANY (LIMITED). — An extraordinary general meeting of this Company was held on Wednesday last at Winchester House, E.C., under the presidency of Sir John Pender, G.C.M.G., M.P., Chairman of the Company, for the purpose of confirming resolutions disposing of the property to a new company in course of formation. The resolutions were confirmed, and Sir John Pender, Mr. F. J. Johnstone, and Mr. Frank W. Bond were appointed liquidators for the formal winding-up of the old company.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The eleventh ordinary general meeting of the shareholders in this Company will be held at the Westminster Palace Hotel, Victoria-street, London, S.W., on Wednesday, the 20th inst., at 12 o'clock. The Directors, subject to audit, have resolved to recommend the shareholders to declare a dividend as follows:—3s. 6d. per share on the 78,949 Ordinary shares of the Company, £3. 10s. paid, and 4s. 3d. per share on the 19,750 £5 fully-paid shares, free of income-tax. This, together with the interim dividend paid on June 20th last, will make a total distribution of 7½ per cent. for the year on the Ordinary £3. 10s. paid shares of the Company.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered the Seven per Cent. Preference shares (Nos. 1 to 12,845) and the Ordinary shares (Nos. 1 to 120,000) of the Electric Construction Company (Limited) to be quoted in the Official List.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—On behalf of this Company Messrs. E. D. Oppert and Co. offer for sale, at £87. 10s. per £100 debenture, £50,000 in £100 debentures, payable £10 on application, £25 on allotment, £25 one month after allotment, and £27. 10s. two months after allotment. The prospectus states that the net revenue of the Company has at all times considerably exceeded the requirements for the service of the whole of the First Mortgage Debentures, and the accounts to June 30th last show a gross income of £18,444, against expenditure of £12,580. The estimated revenue for the Company's current year is expected to considerably exceed that of the previous twelve months, and it is anticipated that it will be sufficient to much more than cover the interest on the present issue of debentures, which are calculated to return 6½ per cent. interest per annum. The bonds are redeemable at par in 1910, if not previously redeemed at £105. The prospectus is not overburdened with particulars, and inquiries should be made by intending investors before subscribing. A copy of the trust deed and the Directors' report and balance-sheet can be obtained from Messrs. Oppert and Co., 33, Old Broad-street, London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 814.—Vol. XXXII. FRIDAY, DECEMBER 22, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

In another column will be found an abstract of the whole discussion on Prof. Forbes' Paper on "Electrical Transmission of Power from Niagara Falls." The Paper should never have been presented to an engineering society, and would have been premature even for a popular audience. The subject, as a practical problem, was clearly quite unripe for discussion. Many of the details were unanimously condemned by practical engineers. Mr. Ferranti's incisive and fearless speech was received with unusual applause, and while we echo his candid statement that no blame can be attached to Prof. Forbes, the important subjects on which he dwelt cannot be allowed to remain where they were left when the meeting rose. The less said about Prof. Forbes' reply the better. To say that the various criticisms have refuted each other is a very old device, and was quite inapplicable to this discussion.

We should like to leave this unpleasant subject alone, but in justice to Mr. Mordey, who was unable to defend himself from the attack made upon him, we must allude to the experiments cited by Prof. Forbes. We happened to be present at Thames Ditton on July 14, 1891, when these or similar experiments on parallel running were made, and we refer our readers to a description of them in the leading article in *The Electrician*, Vol. XXVII., p. 298. We did not learn at the time the precise object in view when a number of Sunbeam lamps were interposed in the circuit connecting the two machines. The result was, however, what might have been expected: that so long as no very great resistance, say half-a-dozen lamps, was used to throttle this circuit, the alternators fell into step as before, even when purposely switched together a little before the moment when they synchronised. But, on increasing this resistance, a time came, as it was obvious it must, when the alternators could no longer hold each other in step. We have no record of this resistance, but have some recollection of eight or nine 100-volt Sunbeam lamps in series, and that when from one-third to one-half of the 2,000 volts were absorbed, the machines began to hunt. But, we ask, what has this got to do with Niagara? What alternators, designed on their own experience by practical dynamo builders, or evolved from the inner consciousness of a consulting engineer, will behave otherwise? We do not ask Prof. Forbes these questions; for all we know he is proposing to put such a resistance into the circuit at Niagara; but we ask our readers to judge of the fairness of using this as an argument on an occasion which gave Mr. Mordey no chance of a reply. We do not for a moment suggest that the machines known as Mordey alternators are suitable for the proposed work at Niagara, and we should be very much surprised if Mr. Mordey, on being asked to design 5,000-H.P. vertical-shaft machines, were to propose to follow his ordinary pattern; but that Prof. Forbes should have thought so does not surprise us.

The article on driving alternators by gas engines, which will be found in another column, calls attention once more to the remarkable difference which exists between the theoretical economy of this source of power and the practical value of its use. Handicapped by the complexity of valves and cams, by the great waste of heat in the water-jacket, and by the cost and clumsiness of an engine which gives only one effective stroke out of four, gas can and does easily compete with steam under certain conditions. If some of these penalties could be removed, the field for competition would be greatly extended. It is only by large flywheels, whether forming part of the dynamo or otherwise, that parallel running with some alternators can be achieved. Gas engines are already seriously loaded with massive wheels, and the limit of size that can be reasonably hung on an armature shaft seems to have been reached. It might be worth while to provide a separate flywheel in a line with the armature shaft, coupled by a flexible coupling, and running, perhaps, on ball bearings. The crude method of governing by omitting explosions is, of course, inadmissible. We are glad to learn that Messrs. Willans and Robinson are taking up the manufacture of gas engines. The result will be watched with the greatest interest, and we cannot do more than hope that it will be equal to their steam engine.

A difference of opinion has arisen between the London County Council and the London Gas Companies as to the precise kind of candle that is supposed to meet the definition of the Metropolitan Gas Acts, namely, "sperm candles of six to the pound, each burning 120 grains an hour." This difference has been settled by the Metropolitan Gas Referees, who have issued a "Notification" prescribing various details of candle making. We learn about the wick that "the strands shall be plaited with such closeness that, when the wick is laid on a rule and extended by a pull just sufficient to straighten it, the number of plaits in 4in. shall not exceed

Digitized by Google

34, nor fall short of 31." We also learn that the *Physeter Macrocephalus* is the precise kind of beast to furnish the spermaceti. From a scientific point of view this notification compares very unfavourably with the Board of Trade instructions for setting up Clark cells; but then we do not regard a standard candle from a scientific point of view. If, at the end of this document, a line had been added, giving authoritatively the value of a candle-power in terms of an amyl-acetate lamp or any other standard, its usefulness would have been increased a thousand-fold.

THE engagement into which a French cable company has just succeeded in bringing the colonies of New South Wales and Queensland for the laying of a cable to New Caledonia is one which we should have thought the home Government had an unquestionable right to veto if it sees fit. The conditions imposed by the French contractors are distinctly matters of "foreign relations," as to which no colony can claim perfect freedom so long as it forms part of the British Empire. The excuse put forward by the Prime Minister of Queensland has nothing to do with the conditions—the escape of New Caledonian criminals being preventible without those conditions. In the event of war between England and France the Government of Queensland would have to break her engagement unless we relieved her of the necessity by breaking the cable. But how about the French operators? They would have to quit the country; and in that case they would leave the cable behind them! Perhaps this is a contingency which the French contractors have not taken into account, though the Queensland Government could hardly have been unmindful of it. We observe that the agreement is for thirty years; we should not like to insure it for as many months.

THE figures supplied by Herr CLARENCE FELDMANN with regard to the working of the Cologne municipal central station for the twelvemonth ending March 31st last, are of no little interest, showing as they do what a Board of Trade unit "made in Germany" may be taken as costing. The output at Cologne for the year 1892-93 was in round figures 307,000 kilowatt-hours, almost the exact output of the House to House Company during 1892, whose station is moreover run on the same system. The total expenses per unit sold at West Brompton were, however, 6·1d., at Cologne 3·29d., or about 14 per cent. better than the *best* London figure, viz., the 3·8d. of the Charing Cross and Strand Electricity Supply Corporation; no money being set aside for depreciation in any of the three cases. Again, in the item of cost of coal per unit metered the Cologne figure of 0·77d. is ahead of our best London stations, viz., the Kensington and Knightsbridge with its 0·92d. and the St. James's with its 0·94d. Another noteworthy fact is that, at Cologne, the units delivered to private houses form only 3·14 per cent. of the total output of the station, whilst shops, restaurants, hotels, clubs, and offices take no less than 83 per cent. The price of gas at Cologne is now 4s. 1d. per thousand, and the average price of the kilowatt-hour about 8d.

THE Compagnie Parisienne de l'Air Comprimé, commonly known as the Popp Company, recently took to supplying its customers' 110-volt lamps with only 95 volts, and as a consequence lost the best part of its *clientèle*, and obliged the Municipal Council, in face of the "intolerable situation" thus created, to allow rival companies to invade the Popp territory. Some five years ago, speaking at the Society of Arts as a private person, knowing nothing whatever about electricity, and merely as one having a few glow lamps in his house, Prof. AYRTON formulated a demand for a light meter as the *ultima thule* of the meter maker; "he did not care anything about watts, or volts, or amperes, or any technical units, but what he did care about was this: he bought light, and he wanted his meter to measure more or less approximately what he was paying for." If the Popp system of extra-low voltage distribution should become general, the demand for a payment-by-result meter would not long be confined to its originator. A 110-volt 16-c.p. lamp run at 95 volts may be taken as equivalent to a 100-volt 16-c.p. lamp run at 86 volts, and would, therefore, give about 5½ candles, or 34 per cent. of its proper light, whilst the consumer's wattmeter would be registering something like 70 per cent. of the original watts. When we have arrived at a light-meter another meter will still be needed before strict justice is meted out. Who can measure the inconvenience caused to unfortunate consumers by supplying their lamps with 14 per cent. less than their proper volts?

WITH almost as great regularity as the tides themselves, but fortunately with a less frequency, proposals are made to utilise by tide-mills the vast power which is "running to waste." A pamphlet sent to us this week is written almost as though the author had made a discovery. One river in the West of England is said to "waste twenty billions of foot-pounds per annum," but every competent engineer who has looked into the matter has found that the prime cost of the works and plant is altogether prohibitive. About ten years ago a patent was granted for utilising a miscellaneous collection of waste energy, amongst others, the audience entering a theatre was expected to generate sufficient electric light for the whole performance, by the rotation of turnstiles at the doors. This is not much more absurd than some tide-mill schemes.

Obituary.—The death is announced of Henry Goebel, the unsuccessful rival of Edison in the matter of the invention of the carbon filament for electric lamps.

The Waddell-Entz Accumulator.—The Hagen Accumulator Company, says *Industries and Iron*, has acquired the sole right to manufacture the Waddell-Entz accumulators in Germany.

Bolton.—The ceremony of laying the foundation stone of the Bolton Corporation electricity buildings took place last week. The scheme adopted is on the alternating-current high-pressure system.

The Joule Memorial Statue.—On Friday, the 8th inst., Lord Kelvin unveiled, in the vestibule of the Manchester Town Hall, a statue of Joule. The movement was promoted by the Manchester Literary and Philosophical Society, and a sum of £2,611 was raised.

The Crompton-Brunton Alternator.—In connection with the notice in our last issue of the Crompton-Brunton alternator, the second point to which special attention has been paid

Digitized by Google

should read "facilities for easily removing and replacing armature coils."

Institution of Civil Engineers.—The Council of this Institution has nominated for election as honorary members the Duke of Devonshire, Dr. Edward Frankland, Capt. Sir Douglas Galton, Prof. von Helmholtz, and the Marquis of Salisbury. At present, out of a gross total of 6,490, there are only 15 honorary members.

Faure's Accumulator Patent in Germany.—The Imperial Court of Appeal at Leipzic has just decided, in an action brought by the Hagen Accumulator Company against certain manufacturers of secondary batteries in Germany, that the employment of lead in the state of super-oxide, oxide, or insoluble salts as a filling material for accumulator plates comes under Faure's patent.

The Telephone in Manchester.—Mr. Haldane Gee recently delivered a lecture on "Electricity in the Service of the City," to a large audience at the New Islington Hall, Ancoats, Manchester. As illustrating the progress of Telephony in Manchester he said that since February, 1891, 2,213 miles of copper and silicium bronze had been used in the New Telephone Company's system. The number of calls for the week ended December 7th last amounted to 80,630.

Oils, Soaps and Electricity (Limited).—A daily paper announces that Messrs. ———— Bros., Limited, "was registered on the 9th inst. with a capital of £10,000 in £10 shares to carry on in the United Kingdom the business of manufacturers of and dealers in cake and other feeding stuff, and oils, soaps, scents, essences, manures and all like products; and also the business of electrical engineers, suppliers of electricity, light, heat and motive power." This reminds one of the story about Roger Giles, who announced that he sold "cocks, hens, owls and other moosical instruments."

The "Telephotos."—Last Friday afternoon Colonel Gouraud delivered a lecture at the United Service Institution on an invention by a Mr. Boughton, of Buffalo, N.Y. The idea is to actuate a number of incandescent lamps placed horizontally or vertically. Colonel Gouraud explained that the theory of the telephotos was the production by incandescent lamps of the symbols of the Morse code, in dashes of 5ft. length made with ten lighted lamps, and dots of 3in. made with one lighted lamp, and with unlighted intervals of 5ft. between each, which will bring under the eye the complete symbol at once, and is intended for use at any points within vision.

Western Union Telegraph Company.—The latest figures published with regard to this gigantic telegraph undertaking show that its growth is satisfactory and steady. In 1892-93 the Western Union Company owned 769,201 miles of wire, or 4 per cent. more than in 1891-92. Messages increased by 6 per cent., the total for 1892-93 being 66,591,858. The gross revenue for 1892-93 was £4,995,688, and the net profit £1,499,207, being an increase of respectively 5·3 per cent. and 1·3 per cent. upon the figures for the preceding twelvemonth. In 1892-93 more than twice as many telegrams were dealt with than in 1879-80, and the revenue was nearly twice as large, but the advance in net profits during that period has only been 28 per cent. The capital of the Company now stands at £20,000,000.

Dublin and Belfast Telephone Trunk Wire.—It is expected that the Dublin and Belfast telephone trunk line will be completed early in January. Already the arrangements as far as Drogheda are perfected, and spoken messages may now be passed between that town and the Irish capital. It will be remembered that Belfast has been coupled up to Glasgow since April last, so that when the line between Dublin and Belfast is completed, it will be possible to communicate verbally between these three great centres of industry. It is not yet stated what the tariff will be, but since the charge between Belfast and Glasgow—a distance of 150 miles which includes 25 miles of submarine cable—is only 1s. per minute, the charge between Dublin and Belfast will probably not exceed this sum. The conductor is a solid copper wire weighing 800lb. to the mile.

Chemical Interchanges.—In a letter to *Nature* on the subject of chemical interchanges in connection with the theory of flame Prof. Armstrong concludes as follows:—"The study of flame affords problems of the highest interest and importance, but of proportionate complexity and difficulty. There is little doubt, however, that we are inclined to take too narrow a view of this as of many other inquiries—that we have an unreasoning belief in what we are pleased to call facts, forgetting that these same 'facts' are but phenomena interpreted by our own limited intelligence. On studying the views that have been taken at various times, it is only too obvious that fashion is not confined only to garments, nor is dogma the exclusive privilege of theologians; and it is time that we realised that very many of our conclusions regarding chemical interchanges are but the crudest dogmas, based on a thoroughly superficial consideration of the phenomena. If we are to deserve the title of scientific workers—workers exact in deed, thought, and word—we must be far more careful in the choice of our language, and guarded in our conclusions."

Refuse Utilisation Scheme for Harrogate.—A scheme of electric lighting by power derived from refuse has been drawn up, and is intended to be tried at Harrogate. The process in outline is as follows:—The refuse is brought in carts or otherwise and tipped upon a platform, whence it is automatically carried into a rough-sifting apparatus which separates the old pots, cans, &c., the smaller material passing through the sifter and into a large hopper, from which it is forced in regular quantities into a drying cylinder which extracts nearly one-third of its weight in the form of moisture. It then passes on to another sifter which takes out the fine dust, the resultant fuel being passed down a shoot and automatically injected into the special boiler furnaces. The dust is said to form a valuable manure, and the consulting engineer thinks that the metal separated from the refuse might be reduced to copperas by a simple process, and the rags will be available for paper manufacture. Electrical engineers will await with interest the practical results of this experiment, the details of which have been drawn up by Mr. George Wilkinson.

Telegraphy in France.—At the end of the year 1892 the entire network of French telegraphs comprised 103,280 kilometres of line, the length of wire amounting to 318,733 kilometres. The apparatus in use included 12,123 Morse instruments, 768 Hughes printing telegraphs, and 4,716 of various other kinds. The number of home telegrams sent in 1892 amounted to 34,820,302, of which 2,163,629 were free messages. The number of telegrams transmitted from France to other countries amounted to 2,726,940, as against 2,623,923 received from abroad. In addition 1,571,168 telegrams were transmitted across the country from frontier to frontier. If we compare these statistics with those of other countries at the same date, we find that in point of the number of miles of line Germany takes the leading place, with 117,871 kilometres, France the second position, while Great Britain could at that date show only 54,337 kilometres. In regard to receipts, however, Great Britain takes precedence of France, the annual receipts of the latter having amounted to £1,466,220, as against £2,486,790 in the first-named country.

Triphase Current Transmission in California.—In the city of Redlands, California, the power house contains at present two 250-kilowatt triphase generators, each directly coupled to the shaft of a Pelton wheel. Though but a short time has elapsed since the plant started, there are now in operation 30 arc lamps about the town and 1,000 incandescents of 16 c.p. Besides these, a concern supplying artificial ice has contracted for 150 H.P. to be delivered twenty-four hours a day for twenty-five years. This is supplied by a 120 kilowatt motor especially designed by the General Electric Company. It has eight poles and runs synchronously with

Digitized by Google

the generators at a speed of 750 revolutions, or 6,000 alternations, a minute. The ice house is four miles and a-half from the power house and the motor is started by first short-circuiting the fields until the machine is brought into synchronism with the generator, and then cutting in the exciter. It has thus far proved perfectly satisfactory and the tests show a high degree of efficiency for the entire plant. No transformers are used except directly at the points where light and power is delivered. The lights and small motors are operated at 110 volts, and the ice company is supplied from a separate circuit.

The Pacific Cable.—In the House of Commons last week Mr. Henniker Heaton asked the Under Secretary of State for the Colonies whether he was aware that a contract was entered into last year, and now completed, between a French cable construction company and the Governments of New South Wales and Queensland for the construction of the first section, from Queensland to New Caledonia, of a proposed Pacific cable to America; whether he was aware that the French Government contributed two-thirds of the subsidy (the remaining one-third having been contributed by the British Colonies aforesaid) on the binding condition that the cable material should be constructed in France, that only French officers and men should be employed to undertake the management and working of the cable during a period of 30 years; whether any remonstrance on the subject had been made to the Governments of New South Wales and Queensland by the Secretary of State for the Colonies; and whether he had any objection to state the nature of the reply from the Prime Minister of Queensland to Lord Ripon's communication. Mr. Buxton stated that the answer to the first three questions was in the affirmative. With regard to the last question, a reply had been received from the Prime Minister of Queensland, in which he pointed out that the cable in question would enable the authorities to prevent much more easily the escape of French criminals from New Caledonia.

Electric Cooking.—The advent of electric cooking apparatus seems likely to evolve a highly-scientific species of cook, with, we may be sure, highly up-to-date notions about the "living wage." "Cookery," we are told by a daily contemporary in a description of the electric process, "is raised from the rule-of-thumb level to that of an exact science by the use of a graduated thermometer. For bread or puff pastry a temperature of 370deg. Fah. is required; for pork, veal, or ordinary pastry, 350deg.; for beef, 340deg."; and so on. All this must mean a table of constants in the kitchen, with possible formulæ with different coefficients for jam tarts, mince pies, and Christmas puddings. Perhaps some method of integrating the specific heats, latent heats, and density of the heterogeneous mass to be cooked will be found necessary before the temperature can be finally determined. This will mean Royal Society Papers on the subject. Besides all this, the cooking appliances are depicted as being fitted with a whole battery of switches, various combinations of which, like the stops on an organ, will be necessary to produce various effects. "Afterwards," says our contemporary, in an account of the destructive distillation of a joint, "four of these switches are turned off, and the heat is applied from one side only." Just think of the high scientific knowledge required in order to be able to manipulate these cookery stops, so as to produce any given thermal distribution on the three Cartesian axes of the kitchen oven!

Flexible Trolleys for Canal Boats.—It would seem from a note of Mr. J. Dennis, in the *Electrical Engineer* of New York, of December 6th, that the recent official trials of an electrically-propelled canal boat were not so entirely successful as we were at first led to understand. In some respects the supplementary trials of the pioneer canal boat, the "F. W. Hawley," at Pittsford, have, says Mr. Dennis, been more satisfactory from a technical view point than the official trial in the presence of Governor Flower and the canal officials. One of the vexatious features of the official trial was the long delay incident to the difficulty in placing the heavily-laden canal boat under the trolley wires. Even when the boat was fairly under way, extreme care in steering was necessary to keep the under-running trolleys in position, and almost no variation from the course under the wires was admissible; and the services of a steam tug were required in making the turn, preparatory to the return voyage. Early in the week following the official trial Mr. Dennis was invited to witness some experiments with improvised flexible trolleys. The flexible trolleys were extremely simple temporary devices, and consisted of insulated copper wires, with hooks at the ends. The trolley arms had been removed, and the wires were connected to the standards. The hooks were passed out to the trolley wires by means of a pike pole, and the motors, reversed, backed the boat out into channel. It was then sent ahead regardless of its position under the trolley wires. The boat was steered from side to side, taking any desired position, no difficulty being experienced with the trolleys. While the Westinghouse engineers are silent regarding the ultimate type of trolley to be used, it is probable that it will consist of an over-running carriage, easily removable in case it is desirable for one boat to pass another going in the same direction; these carriages being connected with the motor by means of a reel of flexible wire.

The Utilisation of Water Power.—A committee consisting of Profs. W. C. Roberts-Austen, W. C. Unwin, G. Forbes and Colonel J. Pennycuick was appointed some time ago, says the *Iron and Coal Trades' Review*, to consider the question of the utilisation of the water power derived from the Periyar Irrigation Works in India; this committee, we understand, has now concluded its investigations and issued its report. The committee is of opinion that by the adoption of the arrangements proposed, motive power can be supplied in the towns of Madras, Madeira and Trichinopoly at an annual cost of £3, £2 and £1. 10s. per horse-power respectively. From Colonel Pennycuick's note on the hydraulic apparatus required, we gather that the water for driving the motors will be brought to them in iron or steel pipes, a separate pipe being provided for each motor or pair of motors. He says that the side slopes of the valley are such that there will be no difficulty in laying the pipes, and that the total fall available is a little over 1,000ft., which he recommends for the sake of economy be divided into two stages of 500ft. each. The calculations that he gives are based on this assumption, and that the length of pipe for each stage will be 1,500ft., for, as the slope is 2½ to 3 vertical to 1 horizontal, the average length of the pipes may be taken as three times the head, and his calculations lead to the result that at the works the capital cost per horse-power would not exceed £4, or the annual charge about 10s. per horse-power. The motors, according to Prof. Unwin, should be either Girard turbines, as used at Turin, or tangent wheels. Prof. Forbes, in his report, deals with the cost of the electrical part of the works, including the generation of electric current and its transmission to certain points, as yet undecided on, and its utilisation at these points. He appends a most exhaustive note on the character of the machinery to be employed, illustrating his arguments by his experience of the experiments between Lauffen and Frankfort in 1891, and his knowledge of the machinery in use at Niagara. Briefly, he decides in favour of an alternating current. He is rather undecided whether the current should be single-phase or two-phase, which he says must depend largely on the uses to which it is to be applied. For general purposes, however, he prefers the two phase system, and bases his further calculations on that, and finally decides that the type of machine required is each motor to be 5,000 horse-power, vertical shaft, generating 50,000 or 40,000 volts, direct frequency, 50 per second, two phases, and says such a machine can be got out at a remarkably low figure. He then deals with the cost of transmission, and concludes his proofs by saying that it seems quite clear that up to a distance of 350 miles, that is to say to Madras, it will be possible to supply electricity at any low pressure suitable for electric lighting or for motive power at a cost of not more than £4 per horse-power per annum including all costs, with a margin for contingencies. Prof. Roberts-Austen deals with the question as to whether it is possible to obtain aluminium by electric energy, and here it is only a question of the material whence the aluminium is to be extracted. The professor has analysed a specimen of corundum from Salem, and found it of high purity, but he had no means of ascertaining whether it is an average sample, and he is therefore unable to say whether the establishment of an aluminium works in the vicinity of Periyar is likely to prove a profitable undertaking or not.

THE DRIVING OF ALTERNATORS BY GAS ENGINES.

BY J. EMERSON DOWSON, M.INST.C.E.

The opinions of electricians seem to be as conflicting on the merits and demerits of continuous and alternating-current systems, as were the opinions of engineers in the days when the "battle of the gauges" was fought. Happily for my peace of mind I am not a partisan of either system, but I am often consulted about the engine-power required for small central stations; and as many of the proposals brought before me are for alternating currents, I have to face the question: Can gas engines be used for driving alternators in parallel? It is admitted that gas power with generator gas is cheaper than steam power, especially in small stations with light day-loads; not only is the fuel consumption less per horse-power used, but the stand-by loss of boilers with light loads, or with no loads at all, is almost entirely avoided. The inducement therefore to adopt gas power is great, and with the best type of gas engines, as now made for electrical work, it is as easy to drive continuous-current machines, as with steam engines; moreover, the dynamos can now be coupled to the engines if necessary. With alternators, however, certain difficulties present themselves, and the solution of them will to a certain extent depend on the co-operation of electricians with the makers of gas engines.

Of course a gas engine can drive one or more alternators, as well as one or more continuous-current machines; but so far as I am aware, two or more gas engines have not been used for driving two or more alternators in parallel. The trial has yet to be made, and let us for a moment consider the difficulties involved. The alternations must be at frequent intervals, and when No. 1 alternator is running with its load on, No. 2 alternator must be brought up to the same voltage, with precisely the same speed as No. 1. With a steam engine there is at least one impulse every stroke, and the admission of steam can be regulated with great nicety, so that with care No. 2 engine and alternator can be put into step with No. 1, and the load is equalised between them.

With a gas engine working on the Otto cycle, there cannot be more than one impulse in four strokes, in each cylinder, and when the engine has a light load (as would be the case with No. 2 alternator before it is connected with No. 1), the impulses would be at still longer intervals. It is obvious that with two cylinders there would be twice as many impulses as with a single cylinder; and that with a double-acting engine the number of impulses would be proportionately increased. With the double-acting engine, however, more oil and more water must be used to prevent overheating of the pistons, and there are twice the number of gas, air, and exhaust valves, as well as twice the number of ignition tubes and valves to keep in order, compared with those of single-acting engines. Therefore the extra number of impulses involves greater complication, in an engine already more complicated than a steam engine, and there is greater wear and tear of delicate cams and other working parts, as well as increased working cost. However ingenious these double-acting engines may be, it is tolerably certain that as they are now made they will not be used to a large extent, and for practical purposes we need only consider the well-known single-acting engines until something better has been devised.

Even in the double-acting engine, as well as in the single acting, the four-stroke cycle is adhered to, and variations in speed, when the engine is running light, have still to be taken account of, although they are not great if heavy fly-wheels are used. I do not for a moment say that alternators in parallel cannot be driven by gas engines. I do not even know that it has been tried, and I am merely pointing out what has to be considered. In the usual way, when No. 2 alternator has to take up the running with No. 1, it would not have any load on, and if the connection were made immediately after an impulse in No. 2 engine, the latter might go on happily; but if the connection were made a little before the impulse there would be the risk that No. 2 engine would not keep step, and might be pulled up by the sudden drag put on it. Such a point can only be settled by a trial on a practical scale, and to insure success it is not unlikely that a temporary load may have to be put on No. 2 alternator, by means of resistances, so as to get a steady speed and voltage before the connection is made with No. 1. This, however, is not a serious matter, as it involves little more than an extra consumption of fuel for a few minutes.

It may be said that all troubles of running in parallel would be avoided if a continuous current were used, but a low-tension current can only be used within a short radius of the central station, and if a high-tension current is used for the distant areas it must be transformed down for the lamps. Then if the current is continuous, the transformers must be moving machines, which have a low efficiency when working with a light load, and moving machinery must also be looked after while running. With an alternating current, however, the transformers are stationary, and the loss with light loads is less than with continuous-current transformers. On the other hand, accumulators cannot be used with alternating currents; there is no reserve of current, and at least one machine must be run however light the load may be. There is also the disadvantage that accumulators cannot be used to keep the engines fully loaded, and when they are driven with light loads their efficiency is low. There are other electrical considerations; but these I will not attempt to deal with, as I merely want to get the general bearings of the case, so far as it concerns the driving of alternators by gas engines.

The use of accumulators, to a moderate extent, is, I believe, important, as they steady the current sent to the lamps, they can serve the day-load, and they can keep the engine or engines connected with them fully loaded; but I know that some electricians consider that these advantages are outweighed by the trouble and loss of current due to the accumulators themselves. It may also be arranged that gas for the engine power, during the hours of light load, should be stored in a gasholder, instead of storing electricity in batteries. For the moment, therefore, I will put the question of storage on one side, and then we shall be left with the comparison that continuous-current machines in parallel are easier to drive, but that high-tension alternating currents are more easily transformed down for the lamps. The *via media* is often the best, and Mr. Rankin Kennedy's proposal that a low-tension continuous current should be taken from one end of the dynamo, and low-tension alternating currents in quadrature from the other end, is at least worth consideration. In this system the continuous current would be used for serving the district near the central station, and for charging accumulators if desired. The low-tension alternating currents would be raised to high pressure, by step-up transformers, and then transformed down for the lamps in the usual way. To prevent the step-up transformers working at a low efficiency, during the hours of light load, transformers of small size could be used during that time.

Mr. Kennedy proposes this system of working for various reasons, electrical and economical, and I have ventured to refer to it because it seems to me to simplify the use of gas engines for producing alternating currents, as it avoids the trouble of driving alternators in parallel. Compared with a continuous-current system, there is the extra cost of the step-up transformers, and the loss of current due to them; but on the other hand, stationary step-down transformers can be used, so that all the moving machinery would be within the central station. At the same time all, or a portion of the light load, could be served from accumulators, and in small stations no engine need work for several hours. On this point I think it worth while to quote Mr. Kennedy, who says: "It is a remarkable fact, not generally known, that a dynamo running from a storage battery, *i.e.*, as a motor converting continuous into quadrature current, can give without heating about twice the output as quadrature current that it can give when worked simply as a dynamo by a belt."

The adoption of the system would seem to depend chiefly on what will be the loss due to the step-up tranformers, but what this loss may be I do not know. I understand, however, that the system has already been tried, and if those who have had actual experience of it will be good enough to make known their results, they will, I am sure, help forward the solution of this important branch of electrical engineering.

COMPENSATION FOR HYSTERESIS.

BY A. B. FIELD AND M. WALKER.

A method of overcoming the ill effects of hysteresis of iron in measuring instruments, similar in principle to those described by M. Abdank Abakanowicz and E. B. Vignoles in *The Electrician* a week or two ago, has been suggested by Prof. Perry, and the following experiments to carry it into effect were conducted in the early part of this year (1893) at Finsbury Technical College :—

The principle of Prof. Perry's method is shown in Fig. 1.

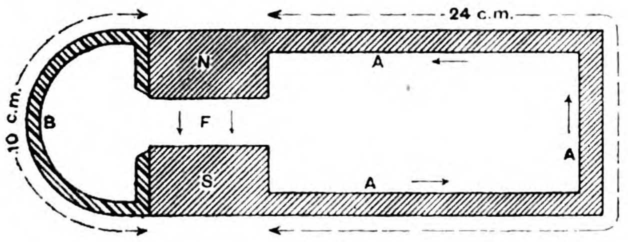

Fig. 1.

A is the iron core of an electromagnet, having its poles at N and S. B is a strip of permanent magnet steel placed as a shunt to the field F. When a current is passed round A, lines of force are generated in A, F, and B of the direction indicated by the arrows. When the current is broken, lines of force due to hysteresis still circulate in A and B in the same direction, and if the length and section of B are chosen (having regard to the greater residual magnetism of the steel), so that the number of lines of force in B shall be equal to the number in A, then none will appear in F.

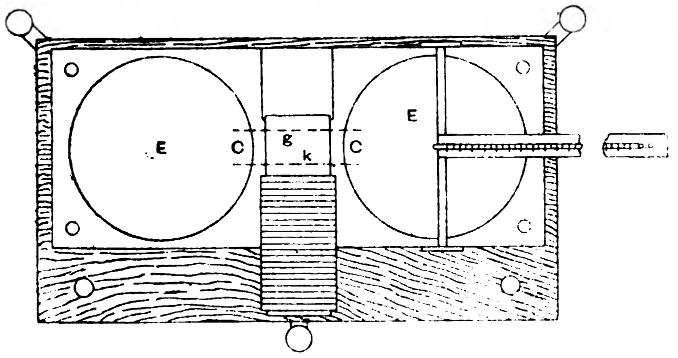

Fig. 2.

Further, it is conceivable that the magnetisation curve of the steel of B might bear such a relation to the magnetisation curve of the iron of A, that at all times during the decreasing of the current the extra induction in A due to hysteresis would be just balanced or taken up by the induction in B. In this way there would be produced, whether increasing or decreasing, a definite field for a definite current, and so long as the straight part of the magnetisation curves were not exceeded, the former would be proportional to the latter.

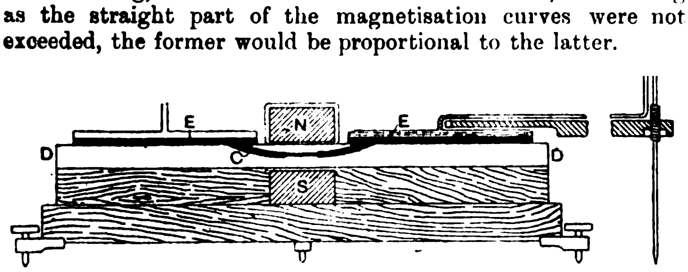

Fig. 3.

Before commencing experiments to practically realise these conditions, it was necessary to have some instrument which would indicate the strength of a magnetic field accurately and at the same time expeditiously. The apparatus which was ultimately constructed for this purpose is shown, in plan, in Fig. 2 and, in sectional elevation, in Fig. 3. N and S are sections of the poles of the iron magnet. C is a little tunnel in the ebonite plate, D D, connecting two large pools of mercury, E E. The section of this tunnel, where it passes through the field to be measured, is rectangular, 1·5cm broad by 2mm deep. To the sides of it, at the points g and k in Fig. 2, were laid conductors, so that current could be made to flow *across* the tunnel. This current, if there is a field between N and S, creates a tendency in the mercury to flow *along* the tunnel from one pool to the other. The pools of mercury are contained in short glass cylinders, one of which communicates with an almost horizontal glass tube about 50cm's in length. A little alcohol placed above the mercury flows along the tube, over a scale, and indicates by its position the pressure exerted by the mercury

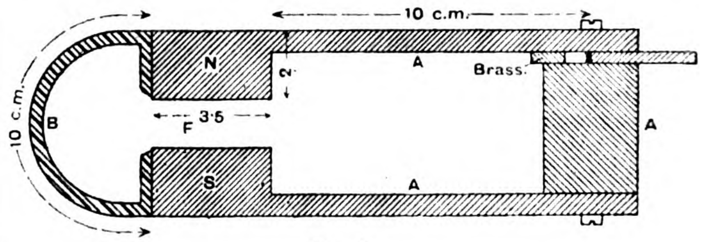

Fig. 4.

carrying the current in the magnetic field. The current through the mercury being constant, this pressure is proportioned to the strength of the field, and it is possible to obtain visible readings for minute variations of the field, whether it be strong or weak.

Experiments were made upon iron cores, of the dimensions and shapes shown in Figs. 1 and 4, by affixing pieces of steel to the ends of the poles as there shown, and taking curves of which the strength of the current passed round the iron were abscissæ, and the strength of the field ordinates, the object in view being to vary the length, section, quality, and temper of the steel, until the curve obtained during the decrease of the current coincided with the curve of increasing current.

One of the best curves obtained is shown in Fig. 5, in which figure is also shown, for the sake of comparison, the curve of the iron alone. It will be seen that the addition of the steel only reduces the strength of field 25 per cent., while the effect of the hysteresis is practically reduced to nothing. The sectional area of the steel in this case was 0·4 that of iron. The break in the iron circuit shown in Fig. 4, was for the following purpose :— It was found that with a continuous core it

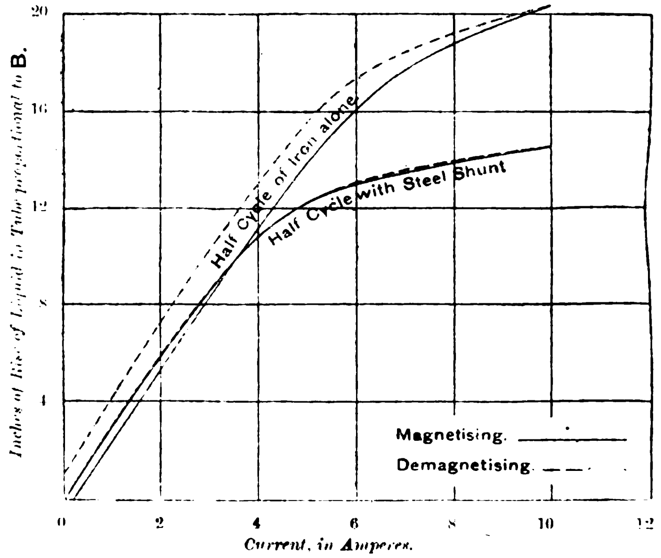

Fig. 5.

was not possible to reduce the effect of hysteresis without using such a large section of steel that the maximum field was reduced to less than one-third. In order to enable a smaller section of steel to be used, the reluctance of the iron circuit was increased by an adjustable gap.

If we consider the residual flux as being due to magnetomotive forces in the iron and steel represented by M and m

respectively, and represent the reluctances of the iron and steel by R and r respectively, then the condition under which there will be no flux across F is $\frac{m}{M} = \frac{r}{R}$, for the flux in A and B is $\frac{M+m}{R+r}$, and if there is no difference of magnetic potential between N and S, $\left(\frac{M+m}{R+r}\right) R - M = 0$. If it is undesirable to decrease r we can make $\frac{r}{R}$ small enough by increasing R. This can be done by the adjustable air-gap, so as to give zero field for zero current, with almost any piece of steel, and the removal of a restriction as to the length and section of the steel facilitates the obtaining of coincidence in other parts of the curve.

The experiments, however, were not wholly successful, for if the current, after being carried to a maximum and reduced to zero, were reversed, and carried to such a value as to reverse the induction in the iron but not in the steel, then the effect in the field F of the hysteresis was as great or greater than if no steel were used. If the current were reversed at all, it was necessary to increase it to the same maximum value as before in order to get satisfactory curves. This mode of neutralising hysteresis, therefore, would only be of service in instruments in which the current is never reversed. If, however, the current, or a fraction of the current, passed round the iron be also passed round the steel it is possible to reverse both simultaneously.

This was tried in several cases, but the introduction of a new variable (namely, the ratio of the ampere turns on the iron to the ampere turns on the steel) made the field of experiment so wide that the investigation was postponed until a time of greater leisure.

SOME FIGURES RELATING TO AN ALTERNATE-CURRENT CENTRAL STATION.

BY CLARENCE P. FELDMANN.

The following is an abstract of the official report of the Municipal Central Station of Cologne, and it covers the twelve months April 1, 1892—March 31, 1893, and forms thus a continuation of the report and description of this station which were published in some of your previous issues.*

The year ending April 1, 1893, shows an increase in the number of lamps connected to the network amounting to 43·7 per cent.; unfortunately, however, the number of kilowatts delivered to the customers has not increased in the same rate. This is due partly to the bad state of trade, and partly to the introduction of the Welsbach burner, &c. Though the statutory price per unit delivered is slightly higher than in most of the other German central stations there is an extremely large difference between the cost of a 16-c.p. incandescent lamp and a split burner of equal lighting power. Table I. shows the relation between the cost of electric and gas lighting for several German towns, the last line of the table relating to the changes which took place at the Cologne Gas, Electric, and Water Works after April 1, 1893. From that day the statutory price of electric energy was reduced from *eight* pfennigs per hectowatt hour to *seven*, while the price of gas per cubic metre remained the same. The apparently higher gas prices of the last line are due to a reduction of the rebates granted to large consumers; the scale of rebates for customers of the electric plant not being altered. Of course, this is a very good plan for increasing the output of an electric central station; and besides, it is not an unjust one, as the numbers of Table I. show; but, unfortunately, it can only be used where gas and electric works go hand in hand.

The total capital invested up to April 1, 1893, was distributed as follows:—

Table II.

	Marks.		Marks.
1. Buildings	424,054	8. Tools and instruments	6,342
2. Engines	223,216	9. Measuring instruments	3,045
3. Dynamos	472,953	10. Furniture	2,603
4. Boilers	124,601	11. Stock of cables, transformers, &c.	17,707
5. Cables	471,640		
6. Transformers	157,903		
7. Electricity meters	34,389		1,948,453

The total energy delivered to the customers which had been 1,549,086 hectowatt hours during the first half-year, October 1, 1891, to March 31, 1892, increased to 3,070,749 hectowatt hours in the last year. As the number of lamps and their distribution are known, and as each consumer has at least one meter, it was possible to compile the figures in Tables III. and IIIa.

With regard to the financial results I am glad to state that the year closed with a net earning of 141,354 marks, which was distributed as follows:—

Interest	64,750	marks
Redemption fund	37,000	„
Fund for renewals..............................	39,604	„
Total	141,354	„

The total output was 3,070,749 hectowatt hours, of which 280,807 were taken up at the station for lighting and testing purposes. The statutory price per hectowatt hour was 8 pfennigs, the price obtained, including the rebate granted to the customers, was 7·66 pfennigs.

THE DANGERS OF THE LEAD INDUSTRIES.

The following is an extract from the Report from the Departmental Committee appointed to inquire into the White Lead and the allied industries. The original committee, appointed in April, 1893, consisted of Mr. J. Henderson, E. Gould, and H. J. Cameron, Inspectors of Factories, Dr. T. Oliver, of Newcastle, A. P. Laurie, and H. J. Tennant, Assistant Private Secretary to the Secretary of State. Dr. A. Dupré was appointed a month later.

X.—Electric Accumulator Works.

57. The Committee are directed to inquire into the use of red lead in electric accumulator works, and to consider whether such works should be included in the special rules they have under their consideration. They visited works in Wolverhampton and London.

The Committee have found this trade, which, judged from the standpoint of most of our staple industries must be said to be still in its infancy, to be conducted in a somewhat crude manner. They trust that ere long much that is now done by hand may be effectively performed by machinery.

The Process.

58. The process consists of rubbing red lead, which has been previously damped with dilute sulphuric acid, and has attained the consistency of clay, on to embossed or perforated leaden plates. The interstices of the plates are thus filled with red-lead mud, so that when finished an even surface is produced.

This is done on both sides of the accumulator plate.

Other plates are similarly treated, litharge instead of red lead being employed.

One man mixes the dry red lead and dry litharge with dilute sulphuric acid, and in this part of the process a considerable amount of dust is produced.

Others rub the red lead or litharge, as the case may be, into the interstices of the plates. They do this with gloves on, using a sort of wooden spatula. But a good deal is rubbed on with the gloves. These latter are put to severe usage and do not last long, and, unless they are in good condition, let the material which is being manipulated through the seams or holes.

A glance at the hands of the worker, when he has taken off his gloves, will at once show whether he has been working with red lead or litharge.

There are other modifications of this method, such as using a piece of lead with small arms branching from it which fits into a mould, and the red lead is put into the mould with it. It is rubbed in tightly with a roller or a small tool, and is put to dry on a tray over an argand burner for a few moments. The piece of metal with red lead adhering to it, in the shape imparted to it by the mould, will readily come away, and the mould can be used over again.

This cake of red lead may sometimes be surrounded by a piece of linen, and it may be mixed with finely-chopped horse-hair to give it a firmer consistency. Another process is to make the red lead clay in the form of square biscuits. For this purpose a mould is also used.

In each of these processes it is necessary for the hands of the workers to be in almost continuous contact with the material used. In some cases gloves were not worn.

Recommendations.

59. The Committee recommend that the person who does the mixing should be obliged to wear a respirator and overall suit, and that all rubbers be obliged to wear gloves and aprons, to be supplied by the occupier, and that the gloves should be inspected constantly by the foreman, and renewed when defective ;* and that there be ample washing accommodation for all in the works, *i.e.*, lavatories with hot and cold water, soap and towels supplied by the firm.

* In order to obviate the three sources of danger mentioned in paragraph 9, page 9, the Committee, in reference to 9 (*a*), cannot recommend that gloves be worn by any *employé* in handling white lead. They have come to the conclusion that although gloves, when well made and sufficiently often renewed, are a fairly effective safeguard in the handling of more or less hard materials, such as blue lead or damp corrosions, their supposed protection is, in a great measure, illusory when the article to be handled is either very moist or very friable and dusty, in both of which conditions it readily penetrates the gloves and comes into contact with the skin under circumstances highly favourable to absorption. Consequently, the Committee cannot recommend their use, nor do they see their way to recommend their abolition in all cases.

XIV.—REMARKS APPLICABLE TO ALL THE FOREGOING TRADES.

Recommendations.

84. The Committee recommend that in all copies of special rules it be made manifest that it is incumbent on the employer to perform what is therein stated to be his duty, and that it is also incumbent on the *employés* to carry out the regulations laid down for their comfort and safety.

It is further necessary that it should be made clear that, for a breach of the rules, the contravener is liable to a fine, or in default to imprisonment; and that this applies to employer and *employé* equally.

In order that there may be no mistake the Committee recommend that every copy of all special rules be headed with the Royal Arms, and that the distinction between "Duties of Occupiers" and "As to Persons Employed" be abolished, "Duties of Persons Employed" being substituted for the latter heading.

There should be a clause at the end of the special rules stating that contravention of these rules involves a liability to a fine not exceeding forty shillings, or in default to imprisonment.

85. The Committee recommend that it be the duty of all occupiers to report to Her Majesty's Inspector of Factories and to the Certifying Surgeon for the district any case of lead poisoning, in the same way as they would at present report an accident.

It has been suggested that the medical attendant of the works should be appointed by the Government, but the Committee, in view of their recommendation that cases of lead poisoning should be reported to the Certifying Surgeon for the district, do not consider it necessary to change the existing system of these appointments.

HYDRAULIC-POWER SUPPLY IN LONDON.*

BY E. B. ELLINGTON, M.INST.C.E.

The Paper first recorded the considerable progress made in the distribution of hydraulic power during the past five years—the number of machines worked from the system in London having risen from 609 in December, 1887, to 1,755 in December, 1892, and the length of mains laid from 27 to 58 miles in the same period, whilst the available horse-power had increased from 800 to 2,600. A public supply was now given in Liverpool, and works were in progress at Birmingham, Manchester, and several foreign towns.

The first pumping-station in London, at Falcon Wharf, Blackfriars, was described by the author in a Paper read before the Institution in 1887. Since that time other pumping stations had been erected at Millbank, near the Houses of Parliament, and at Wapping, near the entrance to the London Docks, while a fourth station was in course of erection at City-road, near the Regent's Canal. The general arrangement of the latter stations was much the same as that at Falcon Wharf, except that at Wapping triple-expansion engines had been employed, with a steam-pressure of 150lb. per square inch. The water used was obtained at Millbank from the gravel bed overlying the London clay. Through this bed about 150ft. of headings had been driven. The water contained iron, which was deposited on exposure to the air. For getting rid of this iron and filtering the water, the Porter-Clark lime process was employed at a cost of 1·05d. per 1,000 gallons. The average output from the station was 1,500,000 gallons per week.

The water at the Wapping pumping-station was obtained partly from the gravel bed, as at Millbank, and partly from the London Dock. The quantity of iron in the water was much less than at Millbank, and the Pulsometer Company's "Torrent" charcoal filters were used at that station. For the purpose of clarification, "alumino-ferric" had been successfully employed. The capacity of the Wapping station was 800,000 gallons in 24 hours. The water used at the several stations was pumped into tanks situated over the engine and boiler houses by pumps worked by hydraulic pressure. These pumps had proved to be economical machines, and possessed the great advantage of being able to work by the pressure in the mains when the main engines and boilers were stopped during the night. The only station worked continuously was that at Falcon Wharf. The total capacity of the accumulators in connection with the system was 1,600 gallons, while the capacity of the pumping-plant was 3,500 gallons per minute. This showed that the accumulators acted almost exclusively as regulators of the pressure, and had little effect in respect of storage.

The results of tests of the Wapping triple-expansion engines and boilers made by Mr. Bryan Donkin, showed a consumption of 1·3lb. of coal per 1 H.P. per hour. The increased economy gained by the use of triple-expansion engines and the high steam pressure of 150lb. per square inch were very striking. At Falcon Wharf, with compound engines working at 85lb. per square inch, 4,048 gallons, at a pressure of 732lb. per square inch, were pumped for every hundredweight of coal consumed. At Millbank, with the same engines, but with 100lb. per square inch of steam pressure, 4,130 gallons, and at Wapping 5,118 gallons, were pumped per hundredweight of coal. The efficiency of the plant in respect of coal consumption, working over long periods, was much below the efficiency of the trial runs, and it appeared that only about 60 per cent. of the coal burnt was utilised at efficiencies obtained in the trials; and 32 per cent. of the balance was wasted by the intermittent running of the plant. Notwithstanding that the total delivery of power had more than doubled since 1887, no diminution of this loss had resulted.

The author proceeded to discuss the question as to whether it was possible to increase this efficiency in practice by improving the load-factors; and especially whether a combination of power-supply during the day and the use of the energy for electric lighting during the night would produce such a result—and arrived at the conclusion that little or no advantage in this respect was to be gained by such combination. The load-factor of the hydraulic supply for the year 1887 was 0·275. For 1889, 0·338, and for 1892, 0·326. It was pointed out that the improvement of the load-factors in recent years over 1887 was due to the enlarged area of supply, and not to the increased quantity of power supplied—the time of maximum demand varying in the different districts supplied. Load-diagrams were given of the electric supply on December 21, 1892 (a foggy day) in Westminster, and of the hydraulic supply on the same day, and the two were combined. The load-factor for the combined curve was 0·522, while the electric load-factor alone was 0·533 and the hydraulic load-factor 0·495. It was further pointed out that under the most favourable conditions a supply approaching the maximum would only be given on 280 days in the course of a year, and that it was impossible, without storage, to obtain from any combination of supplies more than 12 hours' work out of 24—a condition which would only produce a load-factor of 0·380 against 0·325 actually realised. A low load-factor was likely, therefore, to be a permanent cause of low efficiency in all methods of supplying energy which did not admit of extensive storage. The load-factor had, however, a far greater influence upon the amount of capital outlay per unit of output than it had upon the cost of fuel and station expenses.

Particulars were furnished of the actual cost of the supply of hydraulic energy for the years 1884 to 1892 under the headings (1) Station and Distribution Expenses, (2) Repairs, and (3) General Charges. In the result it appeared that the amount of the supply was unlikely to affect the working cost favourably to any substantial extent. The experience of the cost of supply in London showed that the total expenses had increased in direct ratio to the total output, added to a constant representing the minimum cost of working the undertaking irrespective of the output. There was no reason to believe that experience in relation to hydraulic supply in London was likely to differ materially from that of other undertakings established for supplying energy in towns from artificial sources. If works were planned on a moderate scale in relation to the probable output and would allow of extensions as required, the minimum cost of supply would be approximated to within a comparatively short period, and further development was unlikely to exercise any material influence on the cost. The influence of capital expenditure on plant in relation to output was as important as the actual expense in determining the cost at which the consumer could obtain energy. The capital outlay for hydraulic supply in London had fallen from £2·8 per 1,000 gallons in 1885 to £1·24 in 1892, and a further reduction was anticipated in the future.

In conclusion, reference was made to the value of the high-pressure supply for purposes of fire extinction. Attention was also directed to the value of the Pelton water-wheel for high pressures, especially for driving dynamos, in substitution of the hydraulic engines hitherto used. By this apparatus 66 per cent. of the hydraulic energy could be converted into electrical energy, which could be obtained in this way at a cost of about 6d. per Board of Trade unit. The electric lighting of Antwerp was being established on a combined hydraulic and electrical system of this kind, devised by the late Prof. Van Rysselberghe, of Ghent.

* Abstract of a Paper read before the Institution of Civil Engineers, December 19, 1893.

The "Hermite" Process of Sanitation.—M. Hermite, whose electrical sanitation scheme has been described in *The Electrician* in connection with the experiments undertaken by the municipalities of Havre and Lorient in dealing with sewage by electrolysed sea water, visited Worthing by invitation on Saturday last, to make arrangements for a series of experiments. The spot selected as the scene of operations is close to the sea. The experiments will be commenced about a fortnight hence. Speaking of the experiments which are being carried on at Havre, it may be of interest to say that the plant is capable of dealing with sea water at the rate of 132 gallons per minute, under an electrolytic current of from 1,000 to 1,200 amperes. The cost of the process is stated to be about 2 francs per annum per inhabitant

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; and Joseph Wilson Swan, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

THE INSTITUTION OF ELECTRICAL ENGINEERS.

The annual general meeting of the Institution of Electrical Engineers passed off, as usual, with the brief consideration of two or three reforms, but, as usual, nothing was done to materially add to the usefulness of the Institution. So lightly are the suggestions of outsiders taken by the Council at these meetings, that the Annual Report was proposed, seconded, and adopted by mistake, before any remarks were invited upon it. This was, however, soon remedied in so easy-going a body, and what promised to be a stormy attack on the constitution of the Council was opened by Mr. W. T. ANSELL. Taking as his text the memorial which was printed in our last issue, the speaker alluded to the founding of the Society of Telegraph Engineers, complained that telegraph men were not properly represented on the Council, and vigorously urged that at least five members out of the twelve ordinary members of Council should represent telegraphs and telephones. If he had lamented that between 1882 and 1891 there were only 22 Papers on telegraphy, telephony, and earth currents as against 104 Papers on other matters, and had he called upon telegraph men to take part in the proceedings of the Institution, and to sit upon the Council when they were elected, he would perhaps have done more to justify his position. But further debate, and indeed Mr. ANSELL's own speech, was cut short by the dexterous chairmanship of the PRESIDENT, and it remains to be seen whether telegraph men will assert themselves, or, as was significantly hinted, withdraw from the Institution; and whether, if they re-establish, as they have

Digitized by Google

every right to do, the Society of Telegraph Engineers, they will write, read, and discuss those Papers which have been so long conspicuous by their absence.

Differing widely from the first grumbler in lucidity and frankness, Mr. Madgen rose to suggest that the Institution was a mere scientific society, and neglected many matters of profound commercial importance to the electrical trade. Only one sample could be wrung out of Mr. Madgen by the President; this related to the "cutting" of prices for wiring, and he advocated the "rescuing from oblivion" of the wiring rules of the Institution as a remedy. It is quite possible that some of the other matters in Mr. Madgen's mind might have been of too delicate a nature for public discussion, such, for example, as the masquerading of a contractor in the guise of a consulting engineer, but surely Mr. Madgen takes the Institution of Electrical Engineers too seriously. It performs the functions of a scientific society so far as the reception, reading, discussion, and publication of Papers is concerned, and this very imperfectly; but other work on its own initiative, if any there be, is done so modestly, that no one has ever heard of it. The issuing of the wiring rules in 1883 and their revision in 1888 is a solitary exception. These rules have long been obsolete, and even if they are worth remodelling it is doubtful whether the Council elected at the last meeting are better capable of the work than the Councils of 1882, 1888, or the Council of 1889, from whom the Board of Trade invited assistance in connection with the overhead wire regulations. There are seven or eight practical engineers who would no doubt render good service, but they would probably be out-voted by the accumulation of past-Presidents and others. Mr. Madgen had better look elsewhere if he wants anything done. It will be remembered that after the reading of Prof. Fleming's Paper on "The Necessity for a National Standardising Laboratory for Electrical Instruments," in 1885, the author so far roused the meeting as to draw from it a formal request that the Council should consider the best means by which such standardising could be carried into effect; and it was promised in the next annual report that "The matter will accordingly receive the careful attention of your Council." Nothing was done, and it was only when the Electrical Trade Section of the London Chamber of Commerce appointed a committee to attack the subject, and resolved, in January, 1889, to approach the Board of Trade, that somebody remembered that the Council of the Institution of Electrical Engineers had made this promise, and it was thought polite to invite their co-operation. Another brilliant attempt of doing something was the spontaneous appointment of a committee on nomenclature and notation, on May 14, 1885, in connection with Prof. A. Jamieson's Paper on his favourite subject. In the following November, during the discussion on the Paper by Dr. Fleming, to which we have referred, Mr. Swinburne alluded to this committee, but the then President had already forgotten its existence; and, so far as we remember, the matter was, wisely perhaps, never referred to again.

Fruitless attempts are made year after year to induce the Council and officers of the Institution of Electrical Engineers to do for the members what is done by every other learned society, in the distribution of printed copies of the Papers before they are read. Mr. Evershed made a mistake in alluding to the practice of the Institution of Civil Engineers. Attempts on the part of the Electrical Engineers to copy this influential, wealthy, and, we may add, dignified body, are apt to be ridiculous: but, as we have remarked before, the Electrical Institution is now the only one that fails to do its work properly in this respect. The excuse offered by the President was altogether insufficient, but was characteristic of the Institution. He said that the fault lay entirely with the authors, who did not supply the Papers in time. In time for what? All other scientific societies of any repute insist, as a matter of course, that the Papers shall be submitted, generally, in a complete state to the Secretary, but in the less formal societies the author is allowed some indulgence in the way of addenda. The Paper is submitted to one or more members of Council for report, and after it is accepted, it is printed and revised by the author. Not till then is it safe to fix the date for reading. This done, proofs are sent out to members and to outsiders who are likely to take part in the discussion, and, in the case of the Civil Engineers, to any who are known to take an interest in the particular subject. At the Institution of Electrical Engineers it appears that if the author succeeds in seeing his Paper in proof before the meeting he is to be congratulated. Parts of Prof. Forbes' Paper on "Electrical Transmission of Power from Niagara Falls," such as the design of the conduit, or, what is, perhaps, of greater importance, the criticisms on it, are hardly intelligible without illustrations. Six weeks have elapsed since this Paper was read, and yet these have not been issued. To engrave them from no other source than the diagrams shown on the wall could have been done with ease in as many days. We cannot agree that any blame attaches to authors for the shortcomings of the Council or its officers. It was further suggested by the President that beggars cannot be choosers, for since there was such a difficulty in getting Papers at all, authors could not be dictated to. If this be the case, why not reduce the number of meetings? Many members who attend, at some inconvenience, rather lest they should miss something than anxious to listen to anything, would be very glad of a few more free Thursday evenings. The expense of printing, a large item of the annual expenses, would be reduced, and the quality of the remaining Papers might better compare with that of the electrical Papers read before the Institution of Civil Engineers.

Besides eliciting such an unusually large crop of suggestions the Annual Report of the Council contained the announcement that it had been decided to set aside a portion of the invested funds of the Institution for the purpose of forming a building fund. The first meeting of the old Society of Telegraph Engineers took place in February, 1872, so that, under one name or another, the Institution has been in existence close upon two-and-twenty years, and having thus attained its majority may well think of setting about to get a house of its own. Eligible sites are, however, few and far between, and a building worthy of electrical science and engineering will be costly, and it is to be hoped that the Council will not move further until they are amply provided with the wherewithal. No doubt by coalescing with other unhoused societies, the Institution might be provided with quarters, more or less its own, at an earlier date than would otherwise be the case, but if independence in this matter is desirable at all, complete independence should be aimed at.

While comparison with the doings of the Civil Engineers in the matter of circulation of proofs is, we think, not justified, another comparison, and one made by the President, calls for comment. He announced that the Council had carefully considered the question of the mode of election of associates and of members, and had decided that they were unable to make any alterations. The mode, he added, was the same as that of other societies. From this decision of the Council we do not for a moment venture to differ. The matter was deliberately left for their consideration, and they have, no doubt, the best possible reasons for their resolution. But comparison with the procedure of the

Digitized by Google

Institution of Civil Engineers is not warrantable, especially in the case of Associate Members.

The conditions of the Institution of Civil Engineers are as follow:—

Every candidate for election into the class of Associates entitled to the privileges of Corporate Membership shall be more than twenty-five years of age, shall have been regularly educated as a Civil Engineer, and shall be actually engaged at the time of his application for election, in the design or in the construction of such works as are comprised within the profession of a Civil Engineer as defined by the Charter; or,

He shall satisfy the Council that he has had a sufficient training, and that he has been engaged for at least five years, and that he is actually engaged at the time of his application for election, in the design or in the construction of such works as are comprised within the profession of a Civil Engineer as defined by the Charter.

Any person desirous of being elected a member, associate, or honorary member, must be proposed and recommended according to the form A in the appendix, in which the name, usual residence, and qualifications of the candidate shall be distinctly specified. This form must be signed by at least six corporate members certifying a personal knowledge of the candidate, and a full conviction of his qualifications.

The statement of the qualifications of the candidate must embrace a full and complete (though concise) account, in consecutive and chronological order, *with dates*, of the whole of his professional career; including the names of the engineers under whom he served his pupilage, and has subsequently acted; enumerating the nature and extent of the works in or upon which he has been engaged, and the positions he has occupied, and giving an idea of the magnitude and importance of the works of which he has had the charge or the direction.

It is indispensable that the proposer and the seconders should be *personally* acquainted with the professional career of the candidate, and have a full conviction of the "Qualifications" upon which the application is grounded: and no exception can be made in this respect in the case of any candidate who has spent the greater part of his active life abroad. Every member who signs a proposition paper is liable to be called upon to state, specifically and categorically, exactly what he knows of the career of the candidate, and if unable to furnish satisfactory information then the application may be prejudiced.

We do not suggest that such qualifications are desirable in the case of the Institution of Electrical Engineers. The Institution is not strong enough, nor is the profession sufficiently mature. But what we do suggest is, that after these conditions have been complied with, and not before, the voting may be allowed to become a mere form. It is admitted that in the case of the Institution of Electrical Engineers it is a mere form, and yet no more conditions are imposed than for membership of the British Association. The result is that any ironmongers' assistant can acquire the right to affix A.I.E.E. after his name. Of this, the Council, after a twelvemonth, deliberately approves; we need, therefore, say no more.

REVIEWS.

The Incandescent Lamp and its Manufacture. By Gilbert S. Ram. (London: *The Electrician* Printing and Publishing Company. 1893.)

Very little has been written on the manufacture of real lamps, though a great deal of attention has been devoted to such questions as the simple ratio between the power and light of hypothetical lamps and the best efficiency to run them at when the blackening kindly follows a simple law.

The manufacture of incandescent lamps has not been a subject of general interest in this country for many years, for reasons which have been fully regretted in a recent leader in this journal, but it is strange that no books dealing with practical lamp manufacture have appeared in other countries.

The incandescent lamp is simple, but its manufacture is one of the most intricate and difficult examples of scientific industry, and it is understood by very few people, as it is seldom that any one man has both the necessary scientific knowledge and ability and the opportunities for acquiring practical experience. Mr. Ram is exceptionally well qualified, and his book appears just at the right time.

Mr. Ram generally writes from his own experience; but, of course, no one man can have worked practically at all the numerous processes. The result is that his account of some important processes, such as that for making filaments from nitro-cellulose, are rather meagre. Langhans' sulphuric acid process is not mentioned. There is a material called "viscoid" now coming into use in certain trades. It is a homogeneous mass made by coagulating a solution of cellulose. It can be made in thin transparent sheets, and should be very useful for lamp carbons. The Swan process is hardly capable of the highest uniformity. The chapters on the size of filaments and flashing are perhaps the most valuable in the book. They are full of numerical details, which are the result of enormous careful labour, and which cannot be obtained from any other source, as nothing like then has been published before.

There is a certain amount of dry humour about Mr. Ram's style, which always relieves the monotonous accuracy otherwise necessary in a scientific book.

Few scientific men, and no Cambridge man, could write a few chapters of laborious calculations and tables, taking into account all the phenomena of flashing, and could then admit that guesswork in many cases gives as good results. In discussing flashing, Mr. Ram does not seem to realise that a great deal of the fall of resistance is due, not to a highly-conducting coating, but to the heating of the carbon itself. A filament flashed at a high temperature in a vacuum will be found to have become very much harder. Its resistance will be enormously reduced, it will not burn like charcoal in a gas flame, and it will not decompose hot sulphuric acid. Carbons so prepared have been found more durable than after flashing. Whether this is universally true, or is only true of the particular carbon used, is, however, uncertain. It is doubtful how far Mr. Ram is right in saying that measuring the resistance during the act of flashing gives inaccurate results owing to temperature variations of resistance. Carbon varies greatly in specific resistance with changes of temperature, but at high temperatures the variation is much smaller, so that the error he fears should be avoided.

The author's remarks on the difficulty of cheapening lamps by employing substitutes for platinum, which add more to the cost of the lamp in labour and wasters, should be taken to heart by those who are experimenting on sealing alloys.

The question of mercury carrying air and moisture round into a pump so as to spoil the vacuum requires further investigation. Mr. Ram considers it does so. Then, how does a barometer preserve its vacuum for so many years?

Those who use mercury pumps in laboratories should read the chapter on exhausting, as well as Dr. Thompson's Society of Arts lecture. It is safe to say that all the improvements or modifications of mercury pumps, described in various Papers before learned societies, have been used or rejected years before in the various incandescent lamp factories.

Mr. Ram's explanation of the high-efficiency surface fallacy is clear. It was started by Lord Kelvin communicating a Paper by Mr. Mortimer Evans to the Royal Society. It spread like an epidemic, and every lamp maker had a particular kind of surface, which carefully sent out light rays, and held on to heat with more perspicacity than any other lamp makers' surfaces. For years the present reviewer was a minority of one on this point. Now he has at least a companion in solitude.

Mr. Ram's book can be recommended to those interested in the manufacture of incandescent lamps as the only work on the subject which is accurate and up to date. J. S.

A Manual of Electrical Science. By G. J. Burch. (Methuen and Co., London. 1893.)

This little book is one of a series published in connection with the University Extension system. Strange to say, it is free from triviality and cheap erudition, and gives a clear account of the elementary principles of the subject, with many and simple experiments. It fails, perhaps, to comply with the somewhat sententious announcement by the publishers

Digitized by Google

that in this series of books "the subjects will be treated by competent writers in a broad and philosophic spirit." To the competence of the author, who many of our readers will recognise as a late member of the official staff of the Institution of Civil Engineers, we have not a word of objection; but the broad and philosophic spirit so sadly lacking in discourses on Elizabethan Poetry, Psychological Æsthetics and Peruvian Mythology, which form the mental food for omnivorous extension lecture-goers is also absent here. But it is not missed. The historical parts of this book show a great deal of research; the dates of many discoveries are given. As an example of the author's scrupulous accuracy, he traces the supposed share of Madame Galvani in the discovery of the contraction of the frog's leg to a mistranslation in French from Galvani's Latin account. The terms hydrogen sulphate and hydrogen acetate for sulphuric acid and acetic acid may be incontestably correct, but such nomenclature should become well recognised in the general literature of a science before it is employed in elementary handbooks. The treatment of several of the sections are original; an appendix contains a good summary of the C.G.S. system, and is followed by several tables and an index.

Provisional Orders of the Board of Trade. By FRANCIS J. CROWTHER. (London: Jordan and Sons.)

Guides to the maze which has to be trodden by all who are anxious to obtain a Provisional Order are as the sand of the sea-shore, and are for the most part of about the same value. Mr. Crowther's little book will, however, be of use not only to unsophisticated promotors (if any such there be), but should serve to jog the memory even of old parliamentary hands. The numerous and diverse items that have to be attended to between the serving of notices on Local Authorities in June, and the obtaining of Royal assent a twelvemonth or more after, are all set out in order of date, and in a manner calculated to catch the eye. Gas, Water and Tramway Orders are dealt with as well as those relating to electric lighting, with which we are alone concerned.

Kalender für Elektrotechniker, 1894. Edited by F. UPPENBORN. (Munich and Leipzig: R. Oldenbourg.)

In the eleventh issue of this well-known annual publication the sections dealing with iron testing, alternate current measurements, dynamo and transformer testing, glow lamp making, and transmission of power have been revised and extended, and new sections relating to the construction of transformers and electric railways have been introduced. The 106·3 centimetre ohm has been adopted in the resistance tables which have all had to be re-calculated in consequence. We are relieved to see that "Cable Network Calculations" are dismissed in a couple of pages, and to find that there is, at any rate, one German engineer who is of opinion that "the exact calculation of current networks leads to very complicated expressions." For an engineering pocket-book there is, of course, far too much matter, which would be more in place in a treatise; but as the editor admittedly seeks to make his pages of some use to beginners, as well as to practical men, the mistake consists in endeavouring to cover too much ground in a single publication rather than in not realising what sort of information a practical man really wants to have in a handy form.

INSTITUTION OF ELECTRICAL ENGINEERS.

ANNUAL REPORT.

At the meeting of the Institution on Thursday evening last week, the Secretary having read the Annual Report of the Council, the President invited observations from members.

DISCUSSION.

Mr. ANSELL said he rose to ventilate a question which was somewhat a burning one with a very large section of the members. There were very many young members of the Institution present who would probably have much knowledge of himself or of the old telegraphists of 1840-and therefore, by way of preamble, they might permit him to read a memorial which was in course of signature, and which would in due course be presented to the Council. The question at issue was the due representation of all classes of the profession on the Council. Having read the memorial (*see* p. 166 of our last issue) Mr. Ansell proceeded to say that as yet time had not admitted of their obtaining many signatures, but there was no doubt that when the matter was put before them clearly, a great many would adhere to the propositions therein laid down. It was sufficient now to state the idea that was current in their minds, and if the Council would adopt some such plan as they suggested it would go very far to smooth over the irritation which existed. One gentleman, general manager of an influential company, to whom he had spoken upon the subject had replied that the Institution was now so slightly telegraphic that he had lost all interest in it, and he wished therefore to be excused from signing the memorial. That was a feeling that was very widespread, and it behoved the Council to carefully consider their position, for unless telegraph interests were fairly represented—and they did not ask anything which was unreasonable—there would be a very large secession of members from the society. That was not an empty threat; he did not come there to threaten the Council. In support of the memorial he would take leave to be discursive and retrospective. He claimed to be heard because he was the sole living representative in active harness of those who were associated with telegraphic enterprise in 1845, prior to the incorporation of the Electric Telegraph Company. There were five men yet living, but he was the only one in active harness. Of those five one was present that evening, who laid down the first telegraph line that was ever laid in the world, the line between Thorpe and Norwich, the old five-wire telegraph—his old friend Mr. Wilkin, who had done him the honour to come there to support him that night as a representative of the old, old men. It was from the small body of men associated with the old Electric Telegraph Company that had sprung the magnificent institution which they now saw. The oldsters could not hold a candle—nor did they pretend to do—to the modern men of science; they had gone ahead of them. But by virtue of having laid the foundations of what was now a magnificent Institution they claimed to be represented on the Council.

The PRESIDENT (Mr. W. H. Preece) said he thought Mr. Ansell would find that the body of the Institution was with him on this question, and the Council also, and if he would propose that the writers of the memorial should form a committee to consult with the new Council the old Council would certainly advise the members of the new Council to meet the committee and discuss the whole question.

Mr. ANSELL said if the Council would accept the memorial as a basis the memorialists would be delighted to meet the Council, and he hoped they would be able to make some sort of arrangement that would satisfy the requirements of those he represented.

Mr. MADGEN said there were many members of that Institution who were fighting out among themselves very serious practical questions in electrical work which affected the well-being of the industry, and he would like to know if there were no means by which these questions could be brought before the Council and united action taken on behalf of the whole industry. He had been a member for many years, and had listened to the annual reports very attentively; but those reports seemed to mainly concern themselves with the tabulation of the Papers read, the bequests made, and so on, and he did not remember any serious practical question affecting the well-being of the industry being dealt with. He would like to know whether the wiring rules of the Institution were to be rescued from oblivion. It was notorious that wiring was being done at prices at which good, honest, reliable work could not be done. The time might come when this wiring would begin to give way, and some fearful holocaust would draw attention to it in a way that would be likely to do the whole profession incalculable harm.

The PRESIDENT said it was within the province of Mr. Madgen, or of any other member, to submit such a question or any other to the Council. He spoke from some experience when he said that the Council had never received any propositions of that kind without dealing with them properly.

Mr. GROVE suggested that some effort should be made to place copies of the Papers to be read in the hands of the members at an earlier period than they were now obtainable. With their large membership a general distribution might be troublesome and expensive, but he would suggest that if necessary a charge should be made to cover the cost of such a circulation.

The PRESIDENT said there were difficulties in the way of carrying out the suggestion, but the chief of them was the author. If authors would only let them have their Papers a week or two beforehand they might be able to do what was suggested.

Mr. EVERSHED asked what was the practice of the Institution of Civil Engineers, upon which they seemed to endeavour to model their Institution. He was not a member of the Institution of Civil Engineers, but when any Paper on an electrical subject was to be read there the Secretary very kindly forwarded him a copy of the Paper, as doubtless he did to other members of this Institution. If that were done by the Civil Engineers it seemed to him that it ought to be done by their own Institution or their own members.

The PRESIDENT said the Institution of Civil Engineers was a body of 6,000 members, and dealt with every branch of the profession, and they had no difficulty in getting Papers; here, however, the members were few, comparatively, and there was some difficulty in getting Papers, so that they rarely had any in hand. If members would give them plenty of Papers they would have them printed and circulated in time.

The report of the Council was then put to the meeting, and carried.

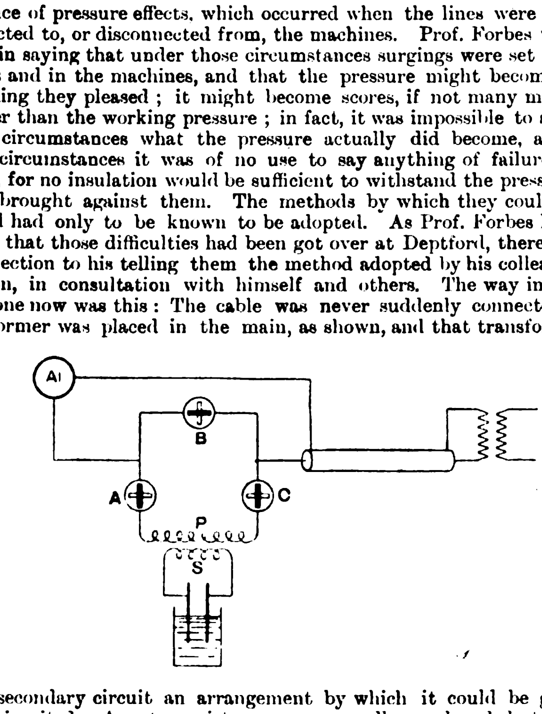
THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.

The following is an abstract of the discussion on Prof. George Forbes's Paper on "The Electrical Transmission of Power from Niagara Falls," which took place at the Institution of Electrical Engineers. Speakers whose remarks are prefaced by an asterisk have returned and revised their abstracts :—

DISCUSSION.

THURSDAY, NOVEMBER 23RD.

*Dr. FLEMING, in opening the discussion, said it was not always that engineers were to be found who were able or willing to take them into their confidence during the constructive stage of their work, and to tell them not merely what they had done, but what they were proposing to do. He would confine his remarks to two points, and the first was the difficulties which might be expected to appear in all cases where electrical transmission of power was conducted over long lines having capacity and self-induction. These difficulties were not merely hypothetical things which were discussed by Professors, and might, therefore, be safely neglected when coming to practice, but were exceedingly real, and capable of giving rise to very disagreeable and dangerous effects. One of the great risks which had to be avoided in the construction of these lines was the presence of pressure effects, which occurred when the lines were suddenly connected to, or disconnected from, the machines. Prof. Forbes was quite right in saying that under those circumstances surgings were set up in the cables and in the machines, and that the pressure might become almost anything they pleased ; it might become scores, if not many more times greater than the working pressure ; in fact, it was impossible to say under some circumstances what the pressure actually did become, and under those circumstances it was of no use to say anything of failure of insulation, for no insulation would be sufficient to withstand the pressures that were brought against them. The methods by which they could be controlled had only to be known to be adopted. As Prof. Forbes had mentioned that those difficulties had been got over at Deptford, there could be no objection to his telling them the method adopted by his colleague, Mr. d'Alton, in consultation with himself and others. The way in which it was done now was this : The cable was never suddenly connected, but a transformer was placed in the main, as shown, and that transformer had



on its secondary circuit an arrangement by which it could be gradually short-circuited. A water resistance was generally employed, but it might be carbon resistance. The first process of connecting the trunk main was to keep the switch B open and close A and C, the transformer being open-circuited on the secondary side. Under these circumstances the transformer offered a considerable impedance to the flow of current, and that nullified the capacity effect in the main. The next step was to gradually short-circuit the secondary circuit of the transformer, reducing the impedance of the transformer. When completely short-circuited the switch B was closed, and then the switches A and C were opened, and the transformer was disconnected from the main. In switching off exactly the reverse took place. When dealing with long concentric cables the capacity might reach a very high value—one-third of a microfarad a mile. It was almost impossible to get a cable, if it was concentric, that had not a capacity effect. If they were to adopt a pressure of 20,000 volts, and a frequency of 100, which was probably what they would have done had they started this enterprise in England, and a capacity of one-third of a microfarad with 18 miles of cable, the capacity current in that cable would be 72 amperes when nothing was connected at the other end. That could be easily calculated from the formulæ he gave some time ago. The capacity of that capacity current to do work, or rather mischief, was proportional to the square of the current and to the frequency. Hence the advantage of low frequencies, for the capacity was something enormous when they came to long lines. Concentric cables were, therefore inadmissable for long lines. He thought there was great safety in using an artificial load in putting machines into and out of parallel. In all Continental stations they did so. When he (Dr. Fleming) was at Rome last Easter he spent a long day with Prof. Mengarini at Tivoli, and the latter allowed him to experiment with the machines there as much as he pleased. They had an artificial load which took up 300 H.P., and this artificial load was made to resemble as closely as possible the real external line. The process of putting the machines in was this : First of all they put them on to the artificial line, and adjusted the incoming machines so as to give exactly the required current and volts. They then put on two machines and divided the current without any difficulty ; then a third was put into parallel, and then a fourth, and a fifth. They were taken out one by one by reversing the process. That artificial line was used in all the Ganz stations, and he thought Prof. Forbes was very wise in making provision for it in dealing with his machines. It was curious that we had not adopted it much in England. He did not know any place where it was used ; yet at the same time he hardly knew any large alternating stations on the Continent where it was not done. In the next place he would say one word on the question of pressure. He was very glad to hear Prof. Forbes say he never intended the primary circuit to be opened. But the question naturally occurred, would not the primary circuit sometimes open itself ? In other words, what was going to be done in the way of main fuses ? That was really a serious question in dealing with these pressures. What kind of main fuses did Prof. Forbes intend to adopt ? In his Paper he mentioned a transformer the secondary of which had a working arrangement which would gradually introduce impedance if the current rose above a certain value. He trusted that that arrangement would be found to work well ; but at the present moment one great want in connection with large distributions of alternating currents was an arrangement of main fuses which would not interrupt the circuit, but if the main current went above a certain value would put impedance into the circuit gradually but quickly, and then take it out again as required, but never allowing the main circuit to be broken. The great difficulty at present was that it *did* become broken, and a great rise of pressure took place, with disastrous results to the insulation. The question of pressure was one to which Prof. Forbes and his colleagues had doubtless given very serious consideration before deciding to adopt 20,000 volts. The difficulty which might be encountered with this high pressure was not the difficulty of working with the stock pressure of 20,000 volts, but the tremendous arcs which might be produced if they were started between the conductors. Prof. Forbes did not tell them, he believed, how far apart those cables were going to be in the conduits. He described a conduit in which copper strip was to be used as the conductor, but did not mention what distance they were to be apart. That was a very important matter. It might be impossible under some circumstances to prevent such rises of pressure that an arc would start, and what would be the state of affairs with naked conductors in those conduits if they were only, say, a foot apart ? The question was sometimes asked, what is the best frequency to work at ? It was very much like asking, what is the best speed to walk at ? It depended upon where you were going and what you wanted to do. Continental engineers had not been at work at the matter at haphazard when they adopted a frequency of between 40 and 50. Our adoption of 80 to 100 was necessitated by the circumstances under which we had to start alternate-current working ; and the same in America. But there was no doubt, he thought, about the wisdom of selecting this low frequency at Niagara, where the utilisation of power by motors was an important matter, and there were enormous advantages to be gained by the reduction of these capacity effects and other effects of the same kind by the employment of a reduced frequency.

* Mr. W. M. MORDEY said they were called upon to discuss a Paper on a subject of world-wide importance, and he believed a sense of responsibility would be felt by all speakers. What made the Paper so interesting was that Prof. Forbes not merely described the scheme and the works but went pretty fully into reasons and principles. It was a very important matter that after so much work had been done on alternate-current distribution of all sorts that Prof. Forbes should come there and throw the gauntlet down to the whole industry on two or three points of primary importance in connection with distribution. Those of them, for instance, who had been working at comparatively high periods had to justify their continued existence and to prove that Prof. Forbes was wrong. Prof. Forbes stated in the Paper that "it is a matter of common knowledge that parallel working is assisted by lowering the frequency." With all respect he (Mr. Mordey) would deny that. He thought there was no evidence whatever to show, with any good plant now running, that lowering the frequency had any connection with parallel working. If there was no difficulty whatever in working at 100 periods there could be no improvement in working at a lower rate. It might be that, with certain types of machines, there were advantages in working at lower rates, but he believed that a machine that was incapable of working at 100 periods would work worse at 16 or 40 periods than a machine that would work at 100 periods successfully. The only definite argument Prof. Forbes put forward was a letter from Messrs. Ganz, who had written him "that their reason in adopting the frequency of 42 periods per second was that it is the lowest frequency that is available with arc lights so as not to produce any serious flickering, and their desire was to lower the frequency as far as practicable in order to ensure parallel working." Now, Messrs. Ganz were very important people ; they had large experience all over the Continent, but it was very necessary to examine and sift statements of this sort, and not to accept them as facts. He thought they ought to ask if Messrs. Ganz had not been a little forgetful in making such a statement as that. In his Paper on alternate-current working in 1889 he made a similar statement ; he quoted a letter by Mr. Zipernowski to *The Electrician* of May 10, 1889, stating that their low periodicity was "chosen on principle," "that we by this means are enabled to couple our dynamos in parallel is not a secondary result, but just the end we are aiming at." His (Mr. Mordey's) surprise was, therefore, very great when during the discussion Mr. Zipernowski wrote : "We state that we have not reduced the periodicity because of the coupling in parallel," and adding that they had always kept to 85 alternations with only slight variations. He happened to know that this last statement was correct. For a considerable time before parallel working Messrs. Ganz had been making alternators of 42 periods per second ; when parallel working was recognised to be a necessity they made experiments and adhered to 42 periods and gave out that they adopted it because it gave the best results in parallel working. I am not aware of any other support than that of Messrs. Ganz to Prof. Forbes's statement, and these words taken from Mr. Zipernowski's own writing showed that his last published statement contradicted

Digitized by Google

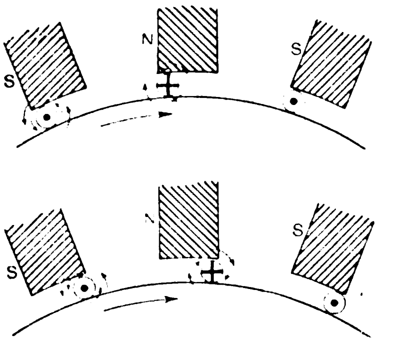
his first, and acknowledged that they had made these machines for low periods for years before parallel working was thought of. The question of artificial loading in putting machines on to mains in parallel had also been dealt with by Prof. Forbes, and had been approved very strongly by Dr. Fleming. Now, that was an old, primitive, and he thought an obsolete method. He explained a plan was got out some years ago by Mr. Rawerth and himself, and published in his Paper "On Testing and Working Alternators," by which the regulation of each alternator was entirely controlled by controlling the steam supplied to its engine. There was another question affecting the periodicity to which Prof. Forbes referred as probably the most important. He said: "I am not sure that it ought not to be said that the greatest advantage of low frequency is in connection with the conductors used for transmission, and in the parts of the apparatus that require high insulation." Then he referred to what was strongly pointed out by Lord Kelvin, and which was found out independently by those wonderful experiments of Prof. Hughes's, namely, the surface effects in conductors at high frequency, the tendency of the current to seek the outside of conductors. That was, no doubt, in low tension alternate-current distribution, an extremely important matter. But in the case of high pressures and long distance transmission he did not think those Hughes effects, as he would call them, were by any means serious, even for the large powers Prof. Forbes proposed. In 1889 he gave a table of the virtual resistances of conductors, based on Lord Kelvin's figures. In the Niagara scheme at 20,000 volts the full current on one of the machines, with 2,000,000 watts, was only 100 amperes. Prof. Forbes selected 350 amperes to the square inch as a suitable density; he thought a larger density would be more economical unless their power was going to be very costly. But taking that density from his table of Lord Kelvin's results he found that at 100 periods per second, or six times as high as Prof. Forbes intended to use his conductor, there was scarcely any Hughes effect at all. Was it worth while going down to 16 or 25 periods per second in order to get this gain? Still, keeping to the subject of low periodicity, they came to the question of transformers. He believed it was impossible by any amount of money, or space, or time, or thought, to make a transformer anything like as good at a low period as at a reasonably high. It was not a question of design or of money. The ordinary idea that they could design a transformer to be equally good under any given set of conditions, so far as periodicity was concerned, was an entire mistake; it was not possible. If they took a transformer made for 16 periods or 40 periods, and ran it at a higher periodicity it would give a very much better result. Prof. Forbes said that by using this low periodicity he had a gain of 3 per cent. more power at his disposal at the other end, and that the transformer only cost about 50 per cent. more. But what did that mean? Prof. Forbes said a transformer would give 132 units instead of 100 if they doubled the frequency, and if the frequency were quadrupled they would get 174 instead of 100. Suppose he took it at double the output, the hysteresis and C^2R losses remained the same, therefore the proportion of the losses had doubled. He had gone down much further than he need have done. He had a triple transformation, first up from his dynamo to his mains, then from his mains down to the 2,000 volt transformers, and then down to 100 volts probably for his motors, for they were going to be worked at low voltages and with transformers. Therefore, there was a triple transformation, and at the very least a sixfold loss. What did he gain? The author supposed that he got a motor that had 3 per cent. more efficiency than if he used a high periodicity one—a supposition that had no sufficient basis. One thing he approved of, and that was the transforming up from the generator. That was very much better than attempting to generate at 20,000 volts. He did not see why they should transform up from 2,000 volts to 20,000; 2,000 was not so safe as 500 volts, and it was just as easy and cheap to transform from 500 to 20,000 as from 2,000 to 20,000. He would pass over what he had intended to say about the commutation of current, but would just say this: Prof. Forbes had, by this low periodicity, cut himself off from the possibility of using the alternate current directly. He had cut himself off from using current directly in any way except for power; he must always transform up to a higher periodicity if he was going to use his power for lighting.

*Mr. GISBERT KAPP said there was one point which struck him on reading the Paper for the first time, where the author was discussing the merits of the number of phases, whether they should have a single phase or two or three phases. When he (Mr. Kapp) was in America in the summer he had a long talk with Prof. Thomson upon this subject. He was very hazy at the time, he must confess, and Prof. Thomson tried to convince him that three phases would require less copper than two. He could not see it then, but he had since studied it, and read all that Dobrowolski and others had written on the subject, and at last he could see light. The result of his investigation was this: Suppose they found the copper in the line weighed 100 tons when a continuous current is employed. If they now worked a different line with the same length and the same efficiency of transmission and the same stress on the insulators with an alternating current, they would double the copper, which would now weigh 200 tons. If they used two phases with four wires they would again require 200 tons; but if they thought to save copper by using only three wires and working two-phases they would require 290 tons, so that the system which Prof. Forbes recommended as the most economical in copper was actually the worst. If they now had three wires, and worked at three-phases, they would use 150 tons only. Two-phase working with three wires was out of the competition altogether; it was too expensive. As regards the motors, he had again the misfortune to differ from Prof. Forbes. The latter thought that the low-frequency motor would be more efficient, and at the end of his Paper a calculation was given to show that the losses in the high frequency motor were 42 per cent. greater than in the low frequency. He quite agreed with the 42 per cent., but he was afraid Prof. Forbes had overlooked the fact that with the high frequency they would have to supply two and a-half times the electromotive force, and it would give two and a-half times the power, and, consequently, what appeared to be an increase in the loss of 42 per cent. became actually a gain of 33 per cent., so that on his own showing the high frequency was the more efficient. One reason which Prof. Forbes had given for the use of low frequency, and which had appealed to him (Mr. Kapp) very strongly, was that you could make a synchronising motor out of any dynamo. If they wanted to rig up a motor quickly they could go and buy a dynamo and set it to work. But when he began to consider what had to be done he saw that it was not so simple. They had to put on two contact rings to begin with. Dynamos were cut very fine nowadays; makers did not give extra room for fancy fittings. Therefore they had to send it out to be fitted with these things by a maker. Supposing they had done this, how were they going to start it? Being a single-phase motor, it would not start by itself, and they must put down a little Tesla motor, or some other, to start it. And if they did that they might as well use the Tesla motor a little larger and run their factory from it. He would like to point out that single and multiphase alternate-current motors were on the market and were very good. The only reason that the impression prevailed in England that they were not to be had, that they were not reliable, and only experimental, was that they placed too much credit on what appeared in the electrical papers. He was afraid the papers were treating them rather badly in this respect. It was the fashion amongst them to cry down multiphase and alternate-current work. He could quite sympathise with the editors; it was an unfortunate thing that they had to take up new subjects and study them in order to write intelligently about them. The ordinary alternating current was bad enough, but when you came to three phases it was really too bad. But they should not cry down these things; let them state what the facts were. He had tested such a motor made by the Oerlikon Company, with the following results: the machine gave on the brake 862 watts, and it ran at a speed of 1,800. The frequency varied from 60 to 67; the commercial efficiency was 60 per cent.; the power factor was 74 per cent.; and at starting the current to produce a torque equal to that at the full output of 1¼ H.P. was 2½ times the normal working current. It was rather inconvenient to have such a large current at starting, but by a very ingenious arrangement, now used all over the Continent, the mains did not feel this large current. There was an auto-transformer with a switch handle, which, at the expense of pressure, gave the extra current which went into the motors and it worked beautifully. The weight of that machine was under 1cwt. per horse-power. There seemed to him to be very strong reasons against the adoption of low frequencies as regards motors, and perhaps not so great, but still sufficient, reasons as regards the transformers; one very strong reason was the cost of the alternator. He had studied the design of Prof. Forbes's alternator very carefully, and he might say at once that he was very pleased to be able to agree with him that it was about the best machine that could be made for the job.

Prof. SILVANUS THOMPSON said that the Paper bristled with points, but he would confine his remarks to one or two. In the first place some rules concerning parallel working were given, or rather some remarks were made about the knowledge, or want of knowledge, upon that which constituted the successful design of machines for working in parallel. Prof. Forbes said: "The rules which govern the construction of machines which shall work well in parallel are not very clearly understood. The only fact which has been perfectly established in practice is that the lower the frequency the more efficient and sure is the parallel working." He, too, felt disposed to dispute this point. He would not dwell upon it—he simply disputed it; it had not yet been established; it might be true, but it had not been established. But he did venture to think that this was not the only fact bearing upon the question of the construction or the design of machines for parallel running. In the first place they knew perfectly well that machines would not run well in parallel if they had weak field magnets, if they had armatures that, with the output that the machine was designed for, would perturb or interfere with the magnetism of the field in any serious way. Further, they knew that they did not get easy working between two alternators of distinctly different types. In this case, if the two alternators were so designed, whether in the placing of their coils, or the shape of their pole-pieces, or the relative positions of coil and pole-pieces, so that the curves of their induction were widely different, one giving a form nearly like a sine curve, and the other giving a curve like a saw-tooth curve, they would not run in parallel. These were points that really were known, and bore largely on the question of design. Further, he would like to point out that they sometimes spoke of the self-induction in the armature, and of the reaction of the armature, as though they were the same sort of thing. There was no doubt whatever that an armature which had no iron in it, or in close proximity to it, would have less self-induction and armature reaction than an armature that had much iron in it, and that iron in close proximity to the coils. But they might have an armature which had much self-induction without necessarily very much armature reaction. It depended upon how the iron was disposed near the armature coils with respect to the approach to the polar parts, and the thing which was disastrous in the design of an alternator for these purposes was the putting of iron into the armature in such a way that the iron acted violently on the magnetism, and pulled it about so that the field became an unsteady one. All this, of course, was contained in those wonderful equations on the action of alternate-current machines which Dr. Hopkinson published about 1884. He (Prof. Thompson) was perfectly well aware that the whole theory of alternate working and parallel running could be dug up from those equations. But it was more to the point if they inquired what was the physical action which went on and made it easy or difficult for two machines to run in parallel when they were placed on the same circuit; and the physical effect was really easy to follow out if described by means of a diagram. If they took one of the ordinary types of alternator, say, for example, the Westinghouse (see

Digitized by Google

diagram). Suppose the armature core to be rotating right-endedly, and they had the wires on the outside, the tendency would be to generate currents which would come toward them as the wire was passing the S pole, and to go away from them as the wire was passing the N pole. That was to



say, the electromotive forces, everything being supposed to be symmetrical, would be at their maxima in those coils, and would die away to nothing exactly half-way between the poles. Suppose they had two such machines, exactly alike in phase with one another. Their electromotive forces were at a maximum at that particular instant, and if there was no lag in the current, no self-induction, they would have the currents also at a maximum at that particular point. Now, suppose they had those two machines coupled together in parallel, the electromotive forces were equal if other things were equal, and there was no tendency for one machine to send a current through the other one either way. Now suppose one was a little behind and the other a little ahead, then the electromotive forces would not necessarily be equal. The consequence would be that the current produced by the two through one another, they would have a load thrown on the leading machine tending to bring it back, and a load tending to bring up the lagging machine. But now suppose that the current in the wires was capable, by reason of the disposition of the iron or anything else, of producing considerable reaction. Now for the receding current, the tendency was to exercise a magnetising force around it which would strengthen the field in front of it, and weaken it behind. As a matter of fact, the question of strengthening the field in front of it, or weakening the field behind it, strengthening the field as a whole, depended upon whether the strengthening or weakening was a maximum when the coil was in front of the pole of the alternator or not. If the maximum was reached when the wire was behind the middle position it considerably strengthened the field, but if the maximum occurred when the wire was in front of the middle position it would weaken the field. The one that was ahead of the other would weaken its field, while the other one would strengthen its field. These two reactions, the one of strengthening, the other of weakening, precisely tended to defeat the tendency of the two machines to get back into parallel; that was say, the back armature reaction would of itself tend to prevent the synchronism to parallel.

*Mr. J. SWINBURNE said the first thing that struck him on reading the Paper was not a purely electrical question, but a commercial one, and that was, what was this power going to cost? What was it going to be sold at, who wanted it, and what were they going to do with it? The cost of the power was not given in the Paper. In time it must become public property, and he could not be asking Prof. Forbes any secret, because villages and Cities were being built and factories started, and he hardly imagined the 'cute Yankee was ready to build villages and start factories without knowing what the power was going to cost. This was rather a curious question, and a rather surprising one when they went into it. In most industries the power used was quite a small proportion of the cost of running a factory, whatever it might be. In others, of course, it was a very large proportion. But in such cases, for instance, as flour milling, the cost of power was really a very small proportion, and it would hardly pay to remove a flour mill to a place where power could be had cheap from a place where labour was cheap. In other cases, such as tearing up wood pulp, of course the cost of power was a much more serious matter. But in dealing with very large power plants it generally came out, unless the load factor was very good indeed, that the cost of coal was not such a serious item as they might expect. Some time ago he worked out a scheme for transmitting power from the Midlands to London, and he found it was very largely a matter of interest, for he found that the interest upon capital was so enormous when compared with the cost of coal that the cost of coal was hardly a factor to be considered at all. There was also another important question in connection with this. They wanted to know who was going to use the power. The problem was entirely different according to whether they wanted to supply small users who required one-tenth of a horse-power, or to run printing machines in a district like Fetter-lane, with 2 or 3 H.P., or to drive aluminium works, where they would want hundreds or thousands of horse-power. The difficulty with medium powers was to start the motors. That did not come in with large powers; it was a small detail then. Referring to the extra output from a double current, there was something in that undoubtedly, and as a matter of interest he would like to mention that the question of the transmission of power for long distances by means of double alternating current was really before electrical engineers as early as 1887. He had nothing to do with it himself, so he had all the more pleasure in mentioning that at Messrs. Crompton's they had an inquiry for a large power transmission in Australia, and they discussed a method and decided that it should be alternating. Mr. R. B. Rogers, then his (Mr. Swinburne's) assistant, suggested that the right way to do it was by double current, winding the armature all over with wire. In fairness to Mr. Tesla and others he must say that he did not think Mr. Rogers realised that this double-current plant would be self-starting, but he quite realised other advantages. But the extra output, which was one of the features mentioned by Mr. Rogers, was a little illusory when they dealt with very large machines. The next thing he ought to remark was the very high infrequency which Prof. Forbes used, an infrequency of 0·04 sec. per period. He would like to add to what Mr. Mordey and others had said about transformers. Everybody who had done much practical designing would wish to protest against the large amount of general statement in the Paper, "all other things being equal," and so on. The whole gist of the matter was in the "all other things being equal." In making a radical alteration such as that the whole comparison turned on the "other things." He protested also against the introduction into a scientific Paper of "well-known facts." Whenever an author said a thing was a well-known fact he was sure to be wrong. As to the flickering of lights, one rather important point ought to be threshed out. Helmholtz was the first, he believed, to investigate the frequency which worried the eye; whether Helmholtz quoted or investigated he was not sure. Helmholtz was concerned with the frequency that worried the ear, and went on from that to the frequency that worried the eye, which he found to be a frequency of 25. It must be borne in mind that the frequency of the flickering in the lamp was always double the frequency of the current, so that would mean, according to Helmholtz, that the eye would stand an alternate-current frequency of 12½. It was very curious that Helmholtz's and Forbes's results did not agree. Prof. Forbes observed a flickering at a frequency of 48, or a frequency in the lamp of 96, whereas Helmholtz said the point of limit was 25, so that there was a very large discrepancy between the observations of electrical engineers and the observations of Helmholtz. As to capacity, Prof. Forbes took a great deal of trouble to eliminate capacity from his system. He (Mr. Swinburne) could not help thinking he was wrong there. As soon as Prof. Forbes had in all those triple and double-current motors he would find he had a whole lot of consuming devices on his circuit to take up lagging current. Capacity in the mains was very much like putting a redressed circuit round the field-magnets. Mr. Crompton and he went into the question of frequency some years ago, and they advocated about the same frequency as Prof. Forbes—about 20. But on looking into the matter they found they were wrong. In the first place, the transformers came out outrageous. In the second place, a point which Prof. Forbes had not mentioned, there was the heating of the field-magnets. If they were going to use very low frequency their pole-pieces would be very broad; the peripheral angle covered was large, and if the pole-pieces were not laminated they would get very hot. If they were laminated in the direction of movement they got over the difficulty of heating due to the Foucault currents in it, but they did not get over the difficulty of the enormous hysteresis loss, and he was not sure that this was not going to be a serious difficulty.

*Mr. S. F. WALKER said with reference to the winking of incandescent lamps, if they used thick filaments they could make the frequency as little as they pleased. He would like to know what the cost of the culvert which Prof. Forbes described was going to be. It appeared to him that town distribution would have to come to that. At present they buried their cables, and they could not be certain what was going to happen to them. Sooner or later faults would be generated; experience in connection with telegraph lines would bear that out. Therefore, he felt confident that sooner or later subways would have to be made for town work, and the conductors would have to be carried so that a man could walk upright and examine them. Of course, the subways might be used for a good many other things. The only question was one of cost, and it was important to know what that would be. The revolving parts in Prof. Forbes's dynamos were very heavy, and the speed seemed to him to be high. He had followed the designs for the bearings and so on very carefully. They could provide for the speed, for the centrifugal force, and the twisting strain on the spindle, which was a most important matter, but there was a big difficulty when they came to provide a steel spindle which was very large, as it would have to be to stand the enormous twisting strain; they could never be quite certain what they got inside. He believed he was correct in saying that, in this country, at any rate, all machines which had such heavy moving masses as this revolved at a very much lower speed, something like one-tenth.

The meeting then adjourned until December 14th.

Thursday, December 14th.

On the discussion upon Prof. Forbes's Paper being resumed,

*Mr. FERRANTI said it was well known that dynamo contractors and designers from all the world over had submitted plans to the Niagara Company. It seemed to him that it would be very hard to design a dynamo which was not in every way the best from the knowledge which the gentlemen of the Cataract Construction Company had had put before them. There were, however, several important features in which the dynamo proposed was novel. One of them was the method of insulating the coils. He had not heard of any other public proposition except that of Prof. Forbes for doing it in that way. It might be interesting to know that in the provisional specification of a patent he (Mr. Ferranti) had abandoned, occurred a passage describing a very similar arrangement. He let that drop, and he thought wisely so. He had had the pleasure lately, even since the last discussion, as well as before the Paper was read, of going round some of the works on the Continent, much as Prof. Forbes and the other engineers of the Cataract Construction had done. Although he thoroughly disagreed with the general design of the machine, he recognised some details of value in it, but these were embodied in the designs sent in by Mr. C. E. L. Brown, of Baden, perhaps the man who had done most towards high-pressure work and long-distance transmission. With regard to the cooling of the bearings, it was a very

Digitized by Google

general practice amongst English and Continental engineers to circulate water continually in the jacket round the bearing, which of course was preferable to throwing water on from a hose according to marine practice, but in this case he should say it would be very effective if water were always left on. There should surely be enough water at Niagara to make this possible. He considered the exciting a large plant like that in series was anything but the best arrangement; he believed the old parallel method of exciting had many points in its favour. The question of transforming up was in practice a very awkward one. It led to many objectionable results, and was especially bad where it was combined with other dynamos working direct on the circuit at high pressure. He believed it was contemplated to make those dynamos of higher pressure than 20,000 volts; then, he supposed, the old ones would have to be re-wound, remodelled, or worked on this objectionable plan. There was, he thought, a very great difference, which might not appear at first sight, between designing dynamos and building them; in fact, a thing which one made one's ordinary daily business, was very different from getting together a collection of all the information which was available in the world, and, then, without any previous knowledge of dynamo design, and especially building, and more especially running, to design a machine which was hoped to fulfil great expectations. With regard to the next point, that of the construction of the line and the voltage to be used, as he understood it, it was proposed to use an electromotive force of 20,000 volts on the assumption that, as at Deptford, there had been used an electromotive force of 10,000 volts; 10,000 volts with one pole to earth, so the safety would be equally great with 20,000 volts and both poles insulated. He thought this was a great fallacy. If they had two cables, both insulated from earth and charged in this way, it was exceedingly unstable and dangerous. If they adopted the safest method of conveying electricity, namely, by concentric cables, then the outer conductor took the same potential as that of the earth. If the two cables were separate they were liable by any accident which might occur in practice to have one put to earth. Then they would have a reversal of strains, the whole theory of 20,000 volts being as easy as 10,000 being upset, and they would have conditions which they had not provided for. Taking this pressure of 20,000 volts, the question was how to insulate it. He read in the paper that a subway had been partly built to carry the cables. The first impression upon his mind, and also the last after carefully considering it, was that that subway would be a very hot place; 10,000 volts was quite alarming enough when it got out of control; 20,000 with big horse-power at the back would, he thought, be worse. He thought it was quite possible if any fault did occur in the subway it would cause a very serious state of affairs in the whole of that subway, or, at any rate, through a considerable portion of it, and it would probably lead to the complete breakdown of the system. Next they had the question of periodicity. He could not agree with the periodicity of 16⅔ per second, or even with a periodicity of 25. He was sure there must be a considerable amount of lighting to be done. Why should this lighting be sacrificed? Was there going to be a proportionate gain in the general working of the system by using such a low periodicity? He did not think there would be. He believed the system adopted by Ganz at Buda-Pesth was a more satisfactory one to work at, somewhere about 40. It certainly rendered both arc and incandescent lighting possible, and was somewhere about the happy medium. With regard to the higher periodicity which they had heard spoken of in connection with this Paper, there were enormous difficulties in working with it. It had been spoken of as though it really was not an important thing; but there were very serious effects. In the first place, the capacity effects were much worse where they had to deal with capacity at this high periodicity, and what was much worse than that again was the magnetic retardation due to the field excited round the conductors. This would be alluded to fully in a Paper shortly to be read, and he would not further touch upon it, except to say that it was a very grave difficulty. He ventured, however, to say that so high a periodicity as 100, or even 86, as at Deptford, would be fatal to an economical working of the system. They came now to a most interesting question—how was electricity to be transmitted to a very great distance, by what method was it going to be done? Was it going to be done by alternating currents or by continuous current? He must say he did not see the faintest chance of its being done with continuous with the present knowledge; but, at the same time, he saw very grave difficulties in the way of doing it by alternating currents.

There was one side of the question which he thought was much more important to the Institution than the periodicity, or the electromotive, or the design of the dynamo. It was the general principle upon which the Cataract Construction Company had obtained its information. They proceeded in an exceedingly clever way. They formed a Commission, asked the greatest scientists of the day to join them, got a room at the City and Guilds Institute at South Kensington, and gave the Commission power to offer prizes, very small ones, and used other means, in fact any means, by which they could draw and collect information. He had had the pleasure of meeting some of the people who had sent in specifications. He himself did not send any. Various schemes were sent in. There were those great scientists, men they would not think of questioning, to give the thing perfect legality, and everybody thought it was a good thing. The information was not sent in by amateurs, but by people who had to make their living by building dynamos or some such articles. One firm spent at least £1,000 in doing it, and they might take it that that money did not represent the whole cost nor the value of the brains of those able men who had been engaged in working out a scheme. Nothing sufficiently satisfactory having been obtained, what was the next step? The engineers of the Company were sent round to the different works on the Continent to gain information, the Company knowing full well all the time that that information was not going to be used to the benefit of those who gave it, or be adequately recompensed. It was upon the information so obtained that the designs and schemes which had been put before the Institution had been got out; it was upon the work of the world, the electrical world, unrecompensed, that the undertaking would be carried out at Niagara. He did not blame Prof. Forbes, but it had been beautifully worked out by the Company, and nearly everybody had fallen into the trap.

*Mr. ALEXANDER SIEMENS said it was only right to the Commission who asked for the tenders that he should put the matter from a different point of view from that represented by Mr. Ferranti. He had not the conditions upon which the tenders were given. He (Mr. Siemens) had the pleasure at the time of speaking to the President of the Commission, who explained to him that the conditions were to be, that the different competitors were to send in detailed designs, and if successful, superintend the construction of the machinery in America for a commission of 2½ per cent. or 5 per cent., he forgot which. Under those conditions they competed, but did not send detailed designs, and as a matter of course, was excluded from the prizes. But he was perfectly certain that nobody who read the conditions under which they tendered could say that it was not from the beginning the intention to construct the whole of the machinery in America. He did not think any question ought to arise about being able to send a current of 20,000 volts through underground cables. He, for one, would be perfectly ready to supply cables that would carry 20,000 volts. Such cables were in daily use at the Frankfurt Exhibition having been supplied by his firm for connecting the transformers in the machinery hall to those in the Maine annexe; the normal working pressure was 20,000 volts, the cables having previously been tested to 40,000 volts. Another point which had been insisted upon was that it was quite out of the question to think that a continuous current could serve for such a transmission. Well he was not so sure about that. Their own project for the Niagara transmission was for continuous current, using machines and motors in series. He was not sure that the Cataract Construction Company would not be converted to the continuous current before they had done.

*Mr. S. EVERSHED said one speaker had spoken of the effect when large solid conductors were used; but Prof. Forbes did not say he was going to used large solid conductors, and he (Mr. Evershed) did not doubt that he would not do so. He showed in his diagram of the subway something which might be taken to be laminated strip conductors, so that the skin effect elaborately discussed by Lord Kelvin would not have any prejudicial effect. But there was one effect which would come in, and it was of vastly more importance, and that was the induction between the conductors, whether solid or laminated. It was easy to work out what the back electromotive force of induction would be for any pair of conductors run at any given distance apart, and he had worked out a few cases, taking the conductors to be 6in. apart, or 12in., or 3ft. He also took the density as 333 amperes per square inch, which he understood the author proposed to use. He found that there was one great argument for using as low a frequency as possible, namely, the enormous inductive drop in the lines if run at the 100 periods of Mr. Mordey. If they had mains of 3 sq. in. in section, as Prof. Forbes would have, and placed those mains 6in. apart, if they ran at 100 periods they would have an inductive E.M.F. of 880 volts per mile. Running at 25 periods this was reduced to 192 volts, while the resistance drop was 27 volts. On that ground alone Prof. Forbes appeared to him to have an unanswerable argument in favour of low frequency in that particular case. The only other point he desired to refer to was the question of coupling in parallel. He wanted, if possible, to get Prof. Forbes to tell them distinctly what were the uses of an artificial load in coupling machines in parallel.

*Mr. CROMPTON said there had been an important omission in the discussion. The question which was of real interest to them was, What would be the cost of power to the users in Buffalo or in the more distant towns? How would it compete with the cost of power produced in those towns? That was the point which would interest him most. He should think many engineers like himself had had such schemes on a smaller scale brought before them, and in the large proportion of cases they were reluctantly obliged to abandon them because the interest on the cost of the plant was so great as to overwhelm the advantages of using water power. He had been forestalled in many of the remarks he would have made by Mr. Ferranti. The barefaced attempt to pick the brains of the world and then to utilise the information gained for the benefit of the American manufacturers was a thing to be admired. He was sorry to say that similar attempts were often made in this country; he spoke feelingly. There were many who had spent their blood and treasure in the perfecting of the mechanical details and the other details of electrical machinery, and who could not get any reward for their labours simply because no system of patent laws could cover every little detail of design. The regular modern habit was for the last comer to pick the brains of the world, so they must not blame the Americans. who were only doing on a large scale what had been done so often before on a small one. With regard to the culvert he would not like to be in that culvert when 20,000 volts were going on. If an arc started at one end of that culvert it would go right up to the other end, the whole eighteen miles, in a very short time. Prof. Forbes was going to use porcelain insulators, and he would ask him if he had made experiments to know what the insulating power of porcelain was. What was good enough for electric telegraphs was not good enough for underground work, and failures had been made by those who without sufficient trial had adopted the material used for aerial insulators for underground work. They had made great improvements, and had now got a material that carried 200 volts satisfactorily; whether they would ever get a material which would carry 20,000 volts was beyond him at present. Oil insulators were supposed to be a great remedy, but he thought there were many there who would agree with him after a long trial that they were entirely useless. He did not think continuous currents had been condemned on sufficient evidence. It was useless for people to

Digitized by Google

get up in that room and say there were no difficulties in the matter of "parallelising" alternators. Grave difficulties did exist, and although Prof. Forbes might minimise them, and probably would, by his low frequency, he would find he had not then got over the great problems that would arise. He did not agree with Mr. Ferranti that 40 periods were good enough to produce good electric lighting. He had seen many of Ganz's stations at 42, and the arc lighting was disgraceful.

Mr. WEEKS asked Prof. Forbes whether his circuits were equally divided on either side, with the lead on one side and the return on the other. Prof. FORBES declined to answer this question.

*Mr. MAVOR said it would be interesting if Prof. Forbes would describe the method proposed for ventilating and drying the tunnel. This was a matter of the greatest importance, as constant atmospheric conditions in such a subway were most difficult to maintain. It was notable that the most severe criticism of the scheme for carrying high-tension currents along bare conductors in a culvert came from the principal exponent of the similar method of conducting low-tension currents. The author has said in his Paper that Mr. Tesla has clearly demonstrated the rapid deterioration of solid insulations with currents of high frequency, but many of these effects are also present with currents of low frequency at an equally high voltage.

Major-Gen. WEBBER said they ought all to feel the greatest sympathy with Prof. Forbes in connection with this Paper from one point of view. He had brought before them a Paper referring to work not yet carried out, and in criticising the account he had been good enough to favour them with they should remember that it was inevitable that modifications would have to be made in carrying out that work.

*Mr. KAPP gave an abstract of a communication from Mr. C. E. L. Brown. Mr. Brown advocated a higher frequency than Prof. Forbes, and with regard to running in parallel said he had been unable to detect any difference between low frequencies such as 15 and up to 100. It was astonishing that even at the present day so much was still said of the difficulty of running alternators, single or multiphase, in parallel. He had run machines of very different types in parallel under the most different conditions, and had never found the slightest difficulty; indeed, he had come to the conclusion that the coupling of alternators in parallel was as easy as, if not easier than, that of direct machines. To adopt the two-phase system using four wires seemed to him a good arrangement, and judging from his own experience none but good results could be obtained. It certainly seemed remarkable, considering the number of designs sent in, many of which were extremely good, that Prof. Forbes should have decided upon about the worst arrangement possible for his machine. He could not imagine a more inconvenient arrangement than the magnetic wheel revolving outside the armature, so that it was impossible to get at the machine while in motion, whilst losing entirely the ventilating effect of the revolving wheel for the cooling down of the armature.

*Prof. FORBES said he had to congratulate them on the fact that that evening's discussion had somewhat redeemed the character of the Institution. Those who had really studied this problem to some extent, who knew what the difficulties were, and where the pitfalls were, must have felt that some of the gentlemen who took part in the discussion on the first night had not even begun to grasp the character of the problem before them. He himself had felt nothing but sorrow for the position of that Institution in having such speeches made on a matter of so much importance. That evening there had been more appreciation shown of the difficulties of the work and of its character generally, and the discussion had been carried on with less show of ignorance. In the discordant views expressed by the various speakers he saw a reflection of the train of reasoning which had been going on in his mind during the years he had devoted to the subject, and he saw the beginning of the workings of the minds of those who would have arrived at different conclusions if they had had longer to think about the matter. He was astonished at the manner in which the question of low frequency had been received. He did not claim for himself one atom of credit for having, after most careful consideration, arrived at the conclusion that the lower the frequency they got in the design of their dynamo the better would it be for the working; but now, after the remarks that had been made, he began to look upon himself almost as if he were the discoverer of low frequency. Before going on to discuss the different speeches he wished to say a few words on a subject which Mr. Ferranti had brought forward, and which had also been alluded to in the technical press. It had been said that the International Commission was a farce, and that those who prepared schemes had been treated unfairly. Mr. Siemens had in a great measure answered this, and he would not delay them by referring to that part of the subject. But it had been said that it was determined to give to the men who furnished the plans which should be adopted the superintendence of the work. He held in his hands a report which he submitted at the time, in which he said that alternating current was to be used, that it was to be of two phases, that 2,000 volts was to be used for the local work, that step-up transformers were to be used to carry it to Buffalo, that the motors were to be synchronising motors, Tesla motors with two phases, and motors with laminated fields and commutators. The International Commission had been absolutely loyal to their compact in giving him the superintendence of this work. The only serious mistake which he made in that report was to recommend the adoption of the Mordey alternators. They knew now that they were not of the right frequency, and that in certain other points they would not suit their purpose. If the discussion had been barren in certain parts, they had at least heard from Dr. Fleming of the methods used at Deptford to overcome electrical resonance, and that was an important point. The endorsement which Dr. Fleming had given to his views he considered to be of great value, and showed that he had given some attention to the subject. When he said that the lines should never be suddenly connected to, or disconnected from, the machine, he said something which other speakers probably considered might be regarded as an axiom. But although it might be the practice in this country, it was absolutely the contrary to the practice in America. Accustomed as Mr. Mordey was to deal only with comparatively small electric-lighting plants, he did not realise what their scheme was to be, and especially he did not realise that theirs was to be a power-distributing plant, and that the electric lighting that was to be done was utterly insignificant compared with the rest of the work. Mr. Mordey's opinion that he (Prof. Forbes) had thrown down the gauntlet to electric-lighting men showed that he did not realise the nature of the problem; his reference to transformers of small horse-power as being applicable to their case also showed it; his willingness to condemn the artificial load on the ground of expense also showed it. With regard to parallel working, Mr. Mordey argued, if 100 periods succeeded, why go down to 25? He (Prof. Forbes) had shown twenty reasons for going down below that. It was true 100 periods would allow of the machines working in parallel without getting out of step. But they wanted more than that; they wanted them to run in step without waste current passing from one to the other, and without breakdown. He did not consider that 100 periods would succeed so well as Mr. Mordey would lead them to believe. Mr. Mordey knew quite well that while his alternator worked nicely in parallel it did not work perfectly; he knew his machine had broken down at times. They at Niagara could not afford to experience such breakdowns as he had met with in his comparatively small machines. Mr. Mordey's alternator did not work well enough for their purpose. He said before deciding whether to adopt it or not tests must be made with high resistance between the dynamos in parallel. Mr. Mordey put in a group of Sunbeam lamps in series. The lamps went up and down with a periodicity of a few seconds. From the moment of those experiments he (Prof. Forbes) felt that the machines were not suitable for their purpose. Mr. Mordey thought artificial loads would introduce greater dangers. He had been utterly unable to see what those dangers were. All he claimed for the artificial load was that it was a help to keep the system from breakdown. They could not afford to have breakdowns. He looked to every possible safeguard that could be devised, even though the expense were something greater. In this case there was no additional expense, because the artificial load when not being used for that purpose was useful for other purposes. Mr. Mordey's remarks about skin resistance would be accurate if they could subdivide the 36 square inches required for the conductors of the first 15,000 H.P. used at 2,000 volts. But they could not get space for the enormous conductors unless they massed them together, and at high frequencies the skin effect would come in. Mr. Mordey's remarks on transformers caused him the most regret, for they showed him how far he was from grasping the problem. He did not appear to realise the work that must be done by consulting engineers. An engineer was very little likely to advise such a scheme until he had every detail worked out to a very large extent. Foreseeing difficulties with manufacturers, he set to work to design transformers of low frequencies for every kind of work for which they wanted them. Designing transformers for special cases and for larger sizes than usual was somewhat laborious work, but the results were quite certain when they knew the quality of iron used. Efficiency was so high as to be of almost no account at all when dealing with the large sizes which they required for their work. With regard to the question of the electromotive force of the dynamos, he really hardly understood Mr. Mordey, who wanted them to use 500 volts. If Mr. Mordey would estimate the section of copper for 50,000 H.P. or so, he would see the difficulties to be met with. That copper section would be about 400 sq. in. He had no doubt Mr. Mordey had never realised that until that moment. He could quite understand that with Mr. Mordey's type of machine it would not do to go above 2,000 volts. But he was surprised that Mr. Mordey was not able to realise these two facts: first, that with a 5,000 H.P. the space taken up by insulation was quite immaterial, and in the second place that if you shirked the difficulty of insulating to 20,000 in the fixed armature of the dynamo you would have to face it when you came to the fixed transformer. Mr. Mordey's remarks on lighting were quite beside the mark. Theirs was not a lighting station. Mr. Kapp had dealt with the relative efficiency of single, alternating, two-phase and three-phase currents, and quoted Prof. Elihu Thomson's views. Prof. Elihu Thomson had submitted to him the whole of his reasons for his statement, and he examined them most carefully, and found that they owed their error to the common American mistake of estimating the size of the conductor by the amount of drop they were going to allow instead of by Lord Kelvin's law of economical section. Mr. Kapp admitted his (Prof. Forbes') proof that the losses in the field of a multiphase motor were increased 42 per cent. in the case of a particular motor when they doubled the frequency, but he claimed that a machine with twice the number of poles running at the same speed gave $2\frac{1}{2}$ times the power. Had it not been Mr. Kapp who said that he would have taken no notice of it. But in both of them they had the same total number of lines of force rotating with the same velocity round and round the armature, generating the same electromotive force in the armature and the same current. There was no difference whatever in the power developed in those two machines, and the 42 per cent. remained as he (Prof. Forbes) had given it. Mr. Kapp said they could not find space to put rings on to a direct-current motor to convert it into a synchronising motor. He (Prof. Forbes) did that last summer with one of the stock machines supplied by the Westinghouse Company. Mr. Kapp said he did not know how he would start that motor. The motor would only require to be started once in several months, yet he had started it without recourse to Tesla motors. Mr. Kapp said he had objections to low frequencies with motors, but he did not give his reasons. He heartily thanked Mr. Kapp for the way in which he spoke of his (Prof. Forbes') machine; he was exceedingly glad that a man of such eminence in designing as Mr. Kapp had spoken so well of the machine. He need hardly say that if he dreamt that the Cataract Construction Company were acting in any unfair way he should cease to be

Digitized by Google

connected with the work. Mr. Ferranti had been good enough to tell them that he had stolen this machine from Mr. C. E. L. Brown. Mr. Brown said it was the worst possible design that could have been devised. He knew it was simply a ridiculous assertion that the design of that machine could be said to be in any sense like that of Mr. Brown: but he was glad to be able so promptly to bring a quotation from Mr. Brown to show that he did not think so. He believed his (Prof. Forbes') machine was the first which had been designed upon a principle which ought always to rule the design of a large machine of a new type of construction where they had not past experience to go upon, and that was that they should reach the most economical efficiency. In this design he had added material until he reached a point at which $60 worth of material did not save 1 H.P. He had found, as the result of experience in trying parallel running with different types and a certain number of different frequencies, that lowering the frequency increased the efficiency, and not only the ease, of parallel working. With regard, further, to Mr. Ferranti's remarks, he denied *in toto* that any person had the right to say that the design of that machine had a plausible resemblance to the design of any machine that was put before the Company. He was seeking to get the best design he possibly could, and in so doing it so happened that he differentiated that machine from any one of those sent in infinitely more than they were differentiated amongst themselves. Mr. Ferranti said he was wrong in saying that 20,000 volts completely insulated was so very good. He (Mr. Ferranti) thought 10,000 volts with one pole to ground was better. He gave as his reason that with the 20,000 volts, if one conductor was put to ground, the whole insulation was reduced to 10,000 volts. Yet he admitted that he had one of his own conductors to ground; suppose the other got put to ground by any means, how many volts insulation would that be reduced to? It might be that by using concentric cables they avoided the chances very much of putting the other one to ground, but there were connections and numbers of other means by which it could be put to ground far more likely when hidden underground than in the subway. They owed some gratitude also to Mr. Evershed for working out the back electromotive force due to the inductive action of the conductors, and for showing them how valuable low frequency was for that reason. Mr. Crompton complained that he had not given the cost. Mr. Crompton might be perfectly sure that when they knew the actual cost down to a penny he would not give him the cost then either. There were some things he could not tell them, but he did not think the Institution had any right to complain of his not having been candid enough. The result of the discussion upon his mind had been, first, astonishment to find that he was a discoverer instead of a plain, straightforward plodder; and in the next place he was impressed by the vast differences of opinion expressed by different members of the Institution. He felt a good deal fortified in all the conclusions he had arrived at by the general result of the criticisms, however opposed to his views they might have appeared to be. It might be premature for him to say so, but he felt now that all those who had entered into the discussion would, with further study of the subject, ultimately arrive at his position. Meanwhile he thanked them heartily for the expression of their opinions; he appreciated their motives, and he appreciated the value of what had been said by some of them. At the same time he could assure them that he had not lost one particle of confidence in the perfect success of the work that was being carried out; in fact, his own opinions had been strongly confirmed by the general result of the discussion.

The PRESIDENT said although the hour was very late he was certain they would not wish to close that meeting and the session without conveying to Prof. Forbes their deep thanks to him for having brought that subject before them, and for having elicited such an important discussion. They had evidence before them that night of Prof. Forbes's enthusiasm and his nervousness, or rather his suppressed anger every now and then had kept him from that fluent defence of his position of which they were more familiar. He was quite certain that if anyone of them had worked for years on a tremendous undertaking like that of Niagara, and had been as severely handled as Prof. Forbes had been, they would not have remained as cool as he had.

LEGAL INTELLIGENCE.

The Medical Battery Company (Limited).

C. B. Harness, Managing Director of the Medical Battery Company, J. M. M'Cully, C. B. Hollier, and Dudley Towers, again surrendered before Mr. Hannay at Marlborough-street Police Court, on Wednesday, to their bail to answer to the charges of having conspired together to obtain money by false pretences from divers persons with intent to defraud.

Dr. HERBERT F. WATERHOUSE, M.D., of Wimpole-street, assistant-surgeon at Charing Cross Hospital and lecturer on operative surgery, said that on April 25th last he was at Brighton, and remembered receiving a telegram, in consequence of which he went to Chingford. He there examined Mr. Ball (who was called last week as a witness). He found him in a very exhausted condition, and he appeared to be in extreme pain. The man was suffering from strangulated hernia, and an immediate operation was necessary. He operated upon him. Mr. Ball complained that he had been roughly treated and put to extreme pain at the Medical Battery Company. There was distinct external evidence of great violence having been used. He judged that Mr. Ball had been suffering from hernia for some months or years. The ordinary way to ascertain whether hernia was reducible was by gentle manipulation. In the condition in which he found Mr. Ball a truss would have been inapplicable, and nothing but the operation could have saved his life.

HORACE GEORGE TURNEY, resident assistant-physician at St. Thomas's Hospital, deposed that about March, 1892, he remembered Mr. Burbage going to see him. He examined him, but did not find him to be suffering from any definite disease or spinal complaint. He had a very high opinion of Mr. Stanley Boyd and Mr. Critchett. He had heard of Matthews, the instrument maker, of Oxford-street, as being a manufacturer of repute.

In reply to Mr. Avory, Dr. TURNEY said he recognised Dr. Lewis Jones as an authority on medical electricity, but he would not yield his own opinion on the subject to him. He wished it to be understood that in making that assertion he did not wish in any way to disparage the position of Dr. Lewis Jones.

Mr. TERRELL: I wish here to state, Sir, that I think it would be advantageous in the interests of justice if Towers were discharged. The evidence against him is not very strong.

Mr. Hannay then discharged Towers, whose real name is Sellman.

ROBERT WILLIAM SELLMAN, professionally known as Dudley Towers, was then called as a witness for the prosecution.

Dr. HENRY LEWIS JONES recalled, was then cross-examined by Mr. AVORY. He said that he had held his appointment at St. Bartholomew's Hospital for nearly two years and a half. The electrical department at that hospital was established about seven years before he went there. There were five or six other hospitals in London which had special departments for electrical treatment. As a fact, up to the present time the medical uses of electricity had been very much neglected by medical men. He would not say that many medical men now disputed the therapeutic effects of electricity. There might be a few who did so. He adhered to the statement made in the Preface of his book on medical electricity as to the neglect of electricity as a curative agent. Two years ago, when he wrote the preface, he believed the medical profession had assumed a contemptuous attitude towards the subject. When he obtained his appointment at St. Bartholomew's he had a competitor for the office named Dr. Arthur Harries. He was aware that Dr. Harries had investigated and reported upon the appliances and belts at the Medical Battery Company's premises. He knew that about March, 1893, an invitation was sent to the members of the Royal Society to visit the premises. He was not aware that the Medical Battery Company offered to pay the expenses of a commission to inquire into the utility of their appliances. The Royal College of Physicians and the Royal College of Surgeons were both invited to visit the Medical Battery Company with the view of an inquiry being made into the utility of the appliances. The Zander Institute existed in London before its appliances were purchased by the Medical Battery Company. He thought the Zander method might be useful. At one time he looked upon Dr. Tibbetts as an authority upon electro-therapeutics. He thought he referred to him in the book he wrote as his being an authority. He agreed that the application of electricity, by statical machines and otherwise, was of great use in the treatment of disease. The statical chair alone was of some use in cases of debility, but not of very much use. He had found that the positive-charge mode of treatment was rather disappointing in its results. In the case of the connected electropathic belt there was a minute electric current. In his opinion the current passed partly over the surface of the skin and partly through the tissues of the body. In evidence in a certain case Lord Kelvin did admit that a certain portion of the current would pass through the body. He (the witness) felt certain that minute currents could not influence the body in any way.

The examination of Sellman was here resumed, and the case was again adjourned till 12 o'clock on Thursday.

THURSDAY, DECEMBER 21ST.

On the hearing of this case being resumed, the cross-examination of Dr. Lewis Jones, superintendent of the electrical department at St. Bartholomew's Hospital, was resumed by Mr. Avory.

The WITNESS said that he had heard of a work by Dr. Beard and Dr. Rockwell, but he should not consider it a first-rate authority. He did not take up the position of Dr. Turney, and say that because it was American it was not an authority. He agreed that the acceptance of the view that electricity was a tonic had wrought a revolution in electro-therapeutics. He did not think that in certain diseases, both medical and surgical, it was of advantage to allow the current, galvanic or faradic, to run for several hours all day or all night. He did not consider that currents sufficiently gentle might be passed through the body for hours, if not for days, consecutively without injury, but with benefit. He was aware that some authorities held a different opinion.

At the conclusion of Dr. Lewis Jones's cross-examination the further hearing of the case was adjourned.

Printing, Telegraph, &c., Company of the Agence Havas v. Grist.

This was an action before Mr. Justice Wills, on Saturday last, to recover a sum of money alleged to be due as calls upon shares taken by the defendant on an underwriting agreement. In the absence of the defendant judgment was given for the plaintiffs for £392 and costs.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's Second Issue Five per Cent. Debentures, due on the 31st instant, will be paid on, and after the 30th instant, at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, E.C. Coupons must be left three clear days for examination.

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's Four per Cent. Guaranteed Debentures, due on the 31st instant, will be paid, on and after the 30th instant, at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, E.C. Coupons must be left three clear days for examination.

CORRESPONDENCE.

MOTIVE POWER AND GEARING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I venture to point out an ambiguity which has crept into the articles by Mr. E. Tremlett Carter on this subject, now appearing in your paper.

In No. 811, p. 111, paragraph "Energy," he makes the statement that "when a force is exerted it must be exerted against another force equally great arising from the external or internal resistance of the body against which the force is exerted." Now, if the resistance be equal to the acting force, balance will occur. The acting force cannot overcome the resistance through any length whatever, and, therefore, no work can be done.

A similar assertion is made in No. 812, p. 135, paragraph "Effort and Resistance," where the following is stated:— "The total effort at any point in the engine is exactly, and always, equal to the total resistance at that point." Here, again, balance must ensue, and the engine cannot work. Work can only be done when one force overcomes another through a distance. If the forces are equal, one cannot overcome the other, and no work can be done.—Yours, &c.,

HORACE J. BRYDON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent, Mr. Horace J. Brydon, has fallen foul of my statements about Newton's Third Law of Motion. If he will carefully study Newton's "Principia," or any reliable treatise on the principles of mechanics, he will find that "Action and Reaction are equal and opposite; and to every Action there must be an equal and opposite Reaction." This is universally true, whether of bodies at rest, in uniform motion, or positively or negatively accelerated. Stated in algebraic form the law becomes

$$E = f + m\,a = R,$$

where E is the effort, f is the external resistance, m the mass particle which receives the acceleration a, and R is the *total* resistance. Mr. Brydon objects to the sign of equality, and would substitute the sign of "is greater than." His statement that "if the forces are equal, one cannot overcome the other and no work can be done," is simply untrue, and opposed to the facts of dynamics. Where young students mostly stumble in their attempts to grapple with the law of effort and resistance, is in not seeing that acceleration and the rate of change of acceleration are totally different things; and that while acceleration must always be finite, the rate of change of acceleration *must* be infinite for every instantaneous finite change of force which may occur. In other words, the very instant a change of force occurs there will be such a change of acceleration as will make the above equation continuously true, and there can be no transition period or state of motion in which it will be, even for an instant, not true.—Yours, &c.,

E. TREMLETT CARTER.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

TENDERS INVITED.—The Corporation of Huddersfied are prepared to receive tenders for wiring, and for the supply of electric light fittings for the Corporation's model lodging-house. Plans and specifications can be had of Mr. A. B. Mountain, the Borough electrical engineer, St. Andrew's-road, Huddersfield, and tenders must be sent in to Mr. Mountain by Saturday, January 6th. Further particulars will be found in our advertisement columns.

——— The Wolverhampton Corporation require tenders for the supply of a complete travelling crane for the electric light station. Tenders must be in before noon on January 2nd.

——— The Wolverhampton Corporation invite tenders for the erection of an electric lighting station in Commercial-road, Wolverhampton. Tenders must be left at the office of the Town Clerk before 5 p.m. on January 1st.

TENDERS INVITED.—The Barnsley Arcade Company (Limited) invite tenders for lighting the Barnsley Arcade and adjoining property by electricity. Particulars can be obtained of Messrs. Wade and Turner, 10, Pitt-street, Barnsley.

——— Mr. J. Townsend, of Wren's Hotel, Briggate, Leeds, requires tenders for fixing the various fittings requisite for the electric lighting of the inside and outside of Wren's Hotel.

TENDERS ACCEPTED.—The tender of Messrs. S. J. Waring and Sons, for the supply of engine, dynamo and electric wiring on the training ship "Conway," has been accepted for £395.

APPOINTMENT.—Mr. Austin Shea, formerly of the Indian Public Works Department, has been appointed Chief Electrical Engineer to the Royal Siamese Public Works Department, and will shortly proceed to Bangkok.

PRESENTATION.—Last week Mr. William Hey, who has recently resigned the position of foreman in the dynamo factory of Messrs. W. T. Goolden and Co., was presented by his *confrères* with a marble timepiece and set of bronze figures, as a token of esteem. The presentation was made by Mr. H. W. Ravenshaw. Mr. Hey returns to Halifax.

AGENCY.—Messrs. Henry Rogers, Sons and Co., of London and Birmingham, have been appointed sole agents for the United Kingdom of the Fonderie et Tréfilerie de Bronze Phosphoreux d'Anderlecht (Montefiore Phosphor-Bronze Works), manufacturers of phosphor-copper, phosphor-bronze, and phosphor wire.

BANKRUPTCY.—Creditors of John Herbert Hale, lately trading at 25, St. Stephen-street, Bristol, as an india-rubber merchant and electrician, must send in their claims to Mr. T. W. Munden, 4, Queen Anne-buildings, Bristol, by January 3, 1894.

——— A receiving order has been issued in the estate of James Cranshaw, trading at 8, St. Mary's Parsonage, Manchester, as an electrical engineer, &c.

RAILWAY EXTENSION.—The extension of the Great Western Railway to Brent and Kingsbridge has been completed, and the line is to be worked on the most approved methods for a single line. The Electric Train Staff system having been adopted, the telephone has been provided between Brent and Avonwick, Carr Bridge, Loddiswell and Kingsbridge, and at several places electric semaphore instruments are provided, showing when a train is approaching, and from which direction it is coming.

MESSRS. CONNOLLY BROTHERS.—This firm have now completed the equipment of their new works at Blackley, Manchester. The works cover more than an acre and a-half, and have been specially adapted for the manufacture of insulating materials and insulated wires and cables. Messrs. Connolly notify that they are starting without any incumbrances in the way of obsolete stock and machinery, and will therefore be able to supply their specialities, in the manufacture of which they have had much experience, with all the latest improvements. Price lists are now ready, and can be obtained on application.

HAZELL'S ANNUAL.—The ninth annual issue of this useful publication has been published by Messrs. Hazell, Watson and Viney. It contains, in addition to an immense amount of general information, special memoirs on subjects of interest to the electrical profession. The book consists of nearly 700 pages, and, from amongst the large number of encyclopædias, directories and similar books published at this season of the year, can be very cordially recommended. Well printed, crammed full of information, "Hazell's Annual" is a marvel of cheapness at the published price of 3s. 6d. Seven maps are included in the 1894 edition.

ABERYSTWITH.—Permission has been granted by the Cardigan County Council to the Bourne and Grant Electricity Supply Company to lay electric lighting mains along the main road from Capel Bangor to Aberystwith, and it is anticipated that before the next summer season the greater part of the town will be lighted by electricity.

AUCKLAND (N.Z.).—The Harbour Board is discussing a project for lighting the Port by Electricity.

AYR.—The Lighting Committee of the Town Council are promised by Mr. Christie a report on the possibility of obtaining water power for electric lighting of the Burgh.

BOLTON.—At the last meeting of the Town Council the proceedings of the Electricity Sub-Committee were approved, including the acceptance of Messrs. Siemens Brothers and Co.'s tender for an enlarged main and of a tender from Messrs. J. and E. Wood for the extension of the foundation rails for the crane at the central station. Mr. Rider, the Council's Electrical Engineer, presented his report as to the progress made at the works, and stated that the only contract now to be let is that for the transformer pits.

BRISTOL.—During the past week the electric light has been burning nightly in the whole of the streets comprised in the area of installation prescribed by the Provisional Order. Gas has not been

Digitized by Google

dispensed with because it usually happens that there are faults to be corrected during the first few weeks after the light has been switched on. In Bristol, however, these have been comparatively few, and the installation is generally regarded as a success. With reference to private lighting considerable further progress has been made during the week. By Sunday next electricity will be used for lighting at St. John's Church, in the city.

BRIXTON.—Electric-avenue, a thoroughfare in the south of London, which the Fyfe-Main Company have specially taken under their care, is being brilliantly illuminated during the present week. The installation consists of 60 Fyfe-Main 2,000-c.p. arcs and 1,200 fairy lamps interspersed amongst the trees in the avenue. Between the columns, which run the entire length of the colonnade, baskets of foliage are placed, lighted by incandescent lamps.

BURTON-ON-TRENT.—The new schoolrooms in connection with the George-street Free Methodist Chapel have recently been completed, and are to be fitted for the electric light. The Assembly Hall will seat 600 persons. The work has been carried out by Messrs. T. Low and Sons from designs by Messrs. Durward, Brown and Gordon.

'BUS LIGHTING.—Some difficulty it appears continues to be experienced by the London General Omnibus Company in lighting their 'busses by electricity. It has been found that the extreme wear and tear caused to the batteries by the constant starting and stopping of the 'busses is so considerable that it will be necessary to rearrange these before the system of lighting can be considered perfect.——Mr. J. G. B. Elliot, secretary of the Omnibus and Tramcar Electric Lighting Company (Limited), writes to state that the batteries supplied by his Company to their conveyances will last more than forty hours without recharging.

CAMBRIDGE.—The Town Council, at their last meeting, resumed the discussion on the report of the Electric Lighting Committee, which recommended that the Cambridge Electric Supply Company be permitted to make certain exceptions to a constant supply (see *The Electrician* of November 17th). After some discussion the matter was again referred back to the Electric Lighting Committee.

CARDIFF.—The Lighting and Electrical Committee of the Town Council held a meeting on Tuesday, at which tenders were received and accepted for 250 lamp columns, lamps, and lamp-holders. It was decided to erect about 40 additional lamps in various parts of the town.

CHELMSFORD.—The re-introduction of the electric light into Chelmsford is certainly not to be effected without considerable discussion. The Town Council last week again considered the matter, the first stumbling block being the question of overhead wires. One member of the Council stated that it was more than likely that, if the Council insisted upon the wires being placed underground, the Chelmsford Electric Lighting Company would be compelled to withdraw their offer. It was ultimately decided to leave the question of underground and overhead wires for the decision of the Board of Trade. The Electric Lighting Company have offered to renew for five years their contract for the public lighting of the town upon the same terms as at present. The present contract expires in 1895, and the Lighting Committee's recommendation that this offer be accepted was approved. With regard to the Provisional Order, it was ultimately decided that the further discussion of the subject should be deferred until the next meeting.

CITY OF LONDON.—The Clerk to the Commissioners of Sewers, at the last meeting of that body, read a letter from the City of London Electric Lighting Company on the subject of the telephone tubes in the electric lighting trenches, and also a letter from the Exchange Telegraph Company asking that, in the event of permission being granted for the use of the pipes laid down by the City of London Electric Lighting Company, the Exchange Company might be included in the licences so as to use the tubes for telegraphs and telephones. The City of London Electric Lighting Company, in their letter, asked that no further delay should take place in regard to the Commissioners giving their consent to the use of the tubes. With regard to the proposed charge of £8 per annum for telephones in the City, the Company thought such a charge was not compatible with the outlay of capital, and pointed out that the reduction of charge to 3,000 telephone subscribers would mean that the proposed cheapening of the electric light to private consumers, who now numbered 25,000, could not be carried out. Mr. Gordon moved that the matter be referred to the Streets Committee, and remarked that there might be some modification in the terms made by the Commissioners, and that the charge for the telephone service should not exceed £10 per annum. The Streets Committee will, therefore, consider the matter

CORK.—The following is the reply of the Corporation to the objections raised by the Board of Trade Inspector to the scheme of the City Tramways Company, as approved by the Corporation:—"(1.) The Corporation is satisfied the branch tram through Marlborough-street will be perfectly safe for the contemplated traffic, and unless this branch be sanctioned, tramway No. 2 (to the Bandon and Passage Railway terminus) will be useless; and the inhabitants of Marlborough-street unanimously petitioned in favour of the tramway being laid through the street. (2.) The pressure of 500 volts as the potential of the electrical current be allowed in propelling the tramcars is set down as a maximum, and no regulations were stated to have been made on the subject by the Board of Trade; that a like maximum potential has been allowed in other towns. But the Corporation will assent to whatever potential may be decided upon within that maximum."

COUNTRY HOUSE LIGHTING.—Messrs. A. A. Campbell Swinton and Co. have recently completed the extensive installation of the electric light at "Chesters," Northumberland, the residence of Mr. N. G. Clayton, of Newcastle. In the house, stables, and offices, 500 incandescent lamps are fitted, and the fixtures are of simple but chaste design throughout. The same firm have in hand the electric lighting of Betteshanger Park, near Dover, for Lord Northbourne.——"Larches," the residence of Mr. J. H. Green, has recently been fitted with the electric light by the London and Lancashire Electric and General Engineering Company. The plant consists of a 3-H.P. Crossley gas engine, a shunt-wound dynamo and Epstein cells. Mr. Albion T. Snell was consulting engineer for the work.

ELECTRIC LIGHT IN HYDE PARK.—At a recent meeting of the St. George's Vestry, the recommendation that the offer of the Westminster Electric Supply Corporation (Limited), to lay, at their own expense, an electric light main across the park to the conveniences by Marble Arch, was accepted; but the Vestry would not pledge themselves as to the minimum of current to be consumed.

FLEETWOOD.—The Improvement Commissioners have considered the tenders received for lighting the town, and the Electric Lighting Committee have recommended that the tender of the Brush Company be accepted. It is contemplated that the complete installation will cost about £11,000. The firms tendering consisted of Siemens Brothers and Co., London; Greenwood and Batley, Leeds; C. A. Parsons and Co., Newcastle; Andrews and Preece, Bradford; and the Brush Company, London. The tenders ranged from £6,500 to £8,700. The question of appointing a consulting engineer in connection with the tenders was raised, and the Committee think the superintendence of the works should be placed in the hands of a competent resident working electrical engineer, who shall have charge of the works during construction and take entire charge of the station and the lighting department generally. It is also recommended that a travelling crane be provided in the station, and that motive-power be provided by means of Producer gas plant; 16-c.p. incandescents are to be used for the ordinary street lighting, and in a few selected places 32-c.p. lamps. The Committee, in recommending the report, state that they are very satisfied with the Brush Company's tender, and that they look forward to a considerable saving in various ways outside the question of actual cost of lighting.

HAMPSTEAD.—In connection with the electric lighting scheme a question has arisen as to the position occupied by the architect. Mr. W. H. Preece, who is advising the Vestry on the whole question, has, according to Mr. Farmer, a member, claimed that Mr. Ardron, the architect, is his assistant, and subject to his instructions. This appears to have concerned Mr. Farmer, who has written to the Vestry, and whose letter has been referred to the Electric Lighting Committee.

HEATON.—Complaint is made that the residents of Heaton (Yorks) are charged by the Shipley Gas Company 3s. 4d. per thousand for gas as against 2s. 3d. paid by the consumers of the Bradford Corporation close by. As no satisfactory reduction can apparently be obtained from the Gas Company, many of the principal residents are agitating for a supply of electric current. A circular has been sent round for signature to the principal consumers.

HEREFORD.—A number of the shops in the high town are to be lighted electrically early in the new year.

KILLARNEY.—For some time past there has been a squabble here as to who shall and shall not supply the electric light. This little difficulty has been overcome by a division of the order between Mr. Leahy (representing the Electric Light Company) and Mr. Santry (for the Gas Company).

LLANDRINDOD.—Messrs. Andrews and Preece have presented a report to the Local Board setting out particulars of two schemes for lighting the district electrically, one for 1,000 8-c.p. lamps, the other for 2,000, the former at a cost of £3,000 and an annual upkeep charge of £450, the latter for about £4,000, with an up-keep of from £500 to £600 a year. A suggestion was made from another quarter that the Board should utilise the water power from the river Ithon. The clerk was directed to obtain further information, which will be placed before the next meeting of the Board.

MILL AND WORKS LIGHTING.—The Lark Roller Flour Mills at Mildenhall are now lighted electrically, the work having been carried out by Messrs. W. J. Crampton and Company.——The whole of the extensive premises of the Uskside Engineering Works have been fitted with the electric light, which it is anticipated will prove

Digitized by Google

cheaper than gas, in addition to offering greater convenience in the departments where overtime is found to be necessary. The London and Lancashire Electric and General Engineering Company have recently completed the over-haul of the mains, engines and machinery at the Bulbourne Works of the Grand Junction Canal Company. Extensive alterations and additions to the plant have been made, including a complete system of electric lighting for the whole of the works, necessitating the provision of extra boiler power. A Davey-Paxman Lancashire-type boiler has been supplied, coupled to one of the Lancashire and London Company's new overtype shunt-wound dynamos. The wiring for the installation is on the new watertight system, devised by Mr. C. N. Russell, the Company's engineer.

NORWICH.—The Town Council have decided to light the Council Chamber and the Committee Room at the Guildhall, together with the Municipal and Sanitary Offices, by electricity, and the City Committee have been authorised to obtain a contract for the installation.

PLATTSBURG (N.S.W.).—The Co-operative Colliery at this place has been equipped with complete electrical apparatus, not only for the pumping plant, but for the signalling apparatus and the lighting of the workings. The Crompton Electrical Supply Company, of Sydney, have supplied and fixed the whole of the machinery.

RICHMOND.—The Town Council resumed the adjourned discussion of the Electric Lighting Committee's report at their last meeting. A resolution that the electric light should be extended to a number of principal streets and roads in the district, and that a contract should be entered into with Messrs. Latimer Clark, Muirhead and Co. for that purpose was discussed; but an amendment that the discussion be postponed till the next meeting of the Council was ultimately adopted by a majority of one vote.

SHIP LIGHTING.—The White Star Line have recently added to their fleet the "Gothic," which has been built by Messrs. Harland and Wolff, of Belfast, and is, with the exception of the "Great Eastern," the largest vessel that has ever entered the Port of London. Her registered tonnage is 7,730 tons, she is 490ft. in length and 55ft. in breadth. She is specially built for the New Zealand frozen mutton trade, with passenger capacity of 110 first class and 130 steerage. The ship is lighted throughout by electricity.

SPANISH INTERNATIONAL EXHIBITION.—An exhibition is to be held at Madrid from May 1st to October 31, 1894, and will be divided into fourteen sections, one being devoted to electricity. Owing to the high price of gas the electric light finds considerable favour in Spanish towns.

STAFFORD.—A Local Government Board enquiry has been held at the Guildhall in connection with the Town Council's application for sanction to borrow £20,000 for electric lighting purposes. Colonel Ducat held the inquiry, and will submit his report in due course.

STIRLING.—Mr. Arnot, electrical engineer to the Glasgow Corporation, has agreed to prepare a report for the guidance of the Stirling Town Council in connection with the application for a Provisional Order by the Caledonian Electric Supply Company.

STOKE-ON-TRENT.—In reference to our "Note" of last week respecting the completion of the extensive installation of the electric light at Stoke Station and the North Stafford Hotel, we understand that the whole of the plant for lighting the station, goods yards, and warehouses has been supplied and erected by the Gülcher Company, and consists of 30 arcs, 10 incandescents, and two direct-driven sets of engines and dynamos, with the necessary boilers. It is expected that the lighting will be completed before Christmas.

TUNBRIDGE WELLS.—The Electric Lighting Committee of the Town Council have recommended (and the Council have adopted the recommendation) that Mr. W. H. Preece be instructed to prepare plans and specifications for the new buildings, machinery, and central station for the town lighting scheme.

WEYBRIDGE.—At the last meeting of the Lighting Inspectors it was decided to accept the offer of the Weybridge Electric Supply Company for the renewal of the lighting contract, subject to the wires being laid under ground.

WOKING.—The Local Board recently considered offers made by the Local Gas Company and the Woking Electric Light Company for lighting the Station Ward. The offer of the Electric Light Company to supply the necessary lamps and fittings for £314. 10s., and for £264 per annum for maintenance, current, lighting, repairs, and renewals, was, after some discussion, accepted. Comparing the systems of the two companies, the result is largely in favour of the offer of the Electric Light Company.

YARMOUTH.—The Local Government Board have sanctioned a loan of £15,000 for carrying out the electric lighting scheme, and have also approved of the site selected for the central station. Mr. Preece has been instructed to prepare the necessary specifications, and the Borough Surveyor's plans have been approved.

COMPANIES' MEETINGS.

Woodhouse and Rawson United (Limited).

The first meeting of the creditors of this Company was held by order of the Court, at Cannon Street Hotel, on Thursday. Mr. C. J. Stewart (Official Receiver and Provisional Liquidator) presided.

The CHAIRMAN said the Official Receiver's observations had been necessarily delayed by reason of the statement of affairs having only been submitted by the Directors on November 30th. The books were in a very imperfect condition, not having been written up for three months, and at the present time there was £28,000 still unaccounted for, but it was stated to represent the differences between the balances of the inter-office accounts of the Company. The Directors had been called upon to furnish further explanations of that deficiency, and until that was done he could not say that he was satisfied that they had a thoroughly correct statement of affairs before them. It was estimated by the Directors that there would be a surplus on the assets of £29,636, but that was qualified by the fact that three of them state "that as regards the values of the plant, stock, and certain of the securities, they are not personally competent to form an opinion, and have accepted the values placed upon them by persons at present engaged in the Company's business, who are in a position to be well informed on the subject," while the manager (Mr. Stutchbury) said, "the valuations placed upon the shares and debentures held by the Company in other companies, the stock-in-trade at the head office and various branches, and the goodwill and patents are considerably over-estimated. He considered that the valuations of the debts appearing due to the Company are also over-estimated." He understood from the receiver for the debenture-holders that in his opinion it is extremely doubtful whether the debenture-holders themselves would receive 20s. in the £. He would give them an instance of how the assets appeared at all events, to be of a doubtful character. The value of the Company's Founders' shares and debentures in the Epstein Electric Accumulator Company stood in the books at £34,150, but for the purpose of the statement of affairs that had been reduced by the Directors to £17,000, so that practically 50 per cent. had been written off. There was a book debt due to Woodhouse and Rawson United from the Epstein Company of £12,978, making a total of £40,000 to be recovered from the Epstein asset. According to the original prospectus, Woodhouse and Rawson United Company appeared to have been formed for the purpose of amalgamating several industrial enterprises engaged in electric lighting, and as far as he could see there was nothing to lead any person to suppose that anything besides industrial business was to be undertaken. It was true that in the Memorandum of Association there was power given to the Company to promote any other companies for the purpose of acquiring property and holding shares and so on, but as far as he could see the objects of the Company as stated in the prospectus were to carry on an industrial business. The gross income of the Company for the first year, ending June 30, 1890, amounted to £109,597, of which £88,000 was obtained from other than industrial enterprises. Therefore, the only gross profit which could be allocated to industrial enterprises was £21,000, the expenditure on account of which was £34,000, leaving a loss on the first year's working of this branch of the business of £13,246. Up to the present time the Official Receiver had not had the opportunity of going into the affairs of Woodhouse and Rawson (Limited), whose business Woodhouse and Rawson United took over, but he had very grave doubts as to whether the profits stated to be earned by the former Company were profits at all of the industrial concern. If that were so the £75,000 paid as goodwill to Woodhouse and Rawson (Limited) ought not to have been paid. Adopting the same principle as for the first year, the second year showed a loss on the industrial business of £43,000, and the third year, 1892, a loss of £129,000. As far as he could see, that which had kept the Company afloat and given the shareholders 15 per cent. for two years was the promotion of other companies. The Official Receiver was of opinion that further inquiry was desirable, and he proposed to apply for the public examination of certain officials of the Company in order to test the declaration. The business before them on that occasion was to decide whether they desired to appoint a liquidator other than the Official Receiver, and a committee of inspection. In conclusion he stated that the directors had been invited to attend that meeting, and perhaps they might like to address the creditors.

Mr. F. L. RAWSON said that as Managing Director of the Company he was responsible to a large extent for its transactions. What the creditors had mainly to consider was, first, whether there existed a good business; and, secondly, whether it was possible by reconstruction to get in their debts. With regard to their interest in the Epstein Company, he said that that Company's patents had cost the inventor and the firm who had acquired some of the foreign patents more than £50,000. The only way in which they could judge of their present value was to show what the cost of them had been, and what the actual prospects were. Before they went into liquidation they were in negotiation with one of the principal firms in this country for the sale of their interest in the Epstein Company for £20,000. Of course, if the thing were disposed of at break-up prices they would get but little for it. The Epstein Company to-day had £4,000 of orders, which they were executing at a good profit, and he had a letter from a first-class firm expressing their willingness to take up the manufacture, the accumulators giving them a large share of the profits, subject to their engineer's report being satisfactory. In the face of these facts he did not think the small price the Directors had put upon that asset was too much. He informed the

Digitized by Google

Directors he did not expect to make a sufficient profit to pay 15 per cent. out of the industrial business during the first three years of the Company's existence. It was always the intention of the Board to build up a big industrial business, and more than one member of the Board threatened to resign unless that was attempted. If the Company were reconstructed he did not see the slightest difficulty in making over £25,000 a year from the business. In order, however, that any scheme for reconstruction might be successful, it would be necessary for the debenture holders to wait. He thought they could be paid off in three years, receiving in the meanwhile 6 per cent. per annum. The Ordinary and Preference shareholders would have to find a certain amount of capital, about 4 per cent. and 2 per cent. respectively. The Five and a-Half per Cent. Debenture Stock holders would, no doubt, only get a comparatively small amount if the Company were broken up, and it was a question whether they should not find a small amount of capital. The assets would remain under the control of the debenture holders, and the creditors and shareholders would not be able to touch them until the debenture holders were paid. His opinion was that the Ordinary creditors should get securities in the new Company for at least 50 per cent., and he thought (and in this he differed from the other Directors) that they should receive the other 50 per cent. of their debt back out of any balance of profit after the shareholders had been paid a 10 per cent. dividend. He had between £40,000 and £50,000; but he should not draw a penny on any of his shares in the new Company until the creditors were paid in full. In his opinion it would be advisable to appoint a committee to assist in the preparation of a reconstruction scheme and he hoped that would be done.

Mr. POPE, Q.C., said he had stuck to the concern in person and by his pocket as long as there was any concern to stick to. As a Director he must take all the blame that attached to him as such, but he was also a large shareholder and creditor, and he should lose, probably, as much as most of those present. His opinion was that whether there was a surplus or not depended upon whether the creditors were patient or not.

Mr. LESLIE (receiver for the debenture holders), in reply to a shareholder, said his firm had prepared the statement of affairs, but they could not vouch for the accuracy of the figures it contained on account of the way in which the books and accounts had been kept.

Mr. BOND then moved: "*That no application be made to the Court for the appointment of a Liquidator other than the Official Receiver.*"

Mr. TILLSLEY seconded, and it was agreed to unanimously.

Mr. Dobson (Reuter's Telegraph Company), Mr. Hampton, Mr. Bond, Mr. C. H. Cox, and Mr. Ellenor were then appointed a committee to act with four shareholders to be appointed at the meeting of contributories for the purposes suggested by the Chairman.

A meeting of the contributories was subsequently held at the same place. Mr. Stewart again presided, and made a similar statement to that put before the creditors.

Dr. DUNCAN said the only chance the shareholders had of getting back anything was by making the promoters, directors, and managing director disgorge and refund the money they had obtained from the shareholders, and which they then squandered by paying dividends out of capital, and in other ways. The only person who would consider their interests in a *bonâ fide* manner and press their claims was the Official Receiver, and he moved his appointment as liquidator.

Mr. WARD seconded.

The CHAIRMAN said he would do what he could for the shareholders, but their prospects did not look very rosy at present.

The formal resolution, that no application be made to the Court to appoint a liquidator other than the Official Receiver, was then carried.

Mr. F. L. RAWSON denied that he had made a huge nest-egg out of the concern for himself, but stated that he had lost his all in it. Since the Company had gone into liquidation he had worked without remuneration to assist the Official Receiver, who he was glad to see appointed liquidator. He felt sure that the examinations which would follow from Mr. Stewart's appointment would result in clearing his character in such a way as could not otherwise be done.

Mr. ABRAHAM said what they now had to inquire into was whether the proceedings of the Directors had not been *ultra vires.* He considered that Mr. Pope had all along behaved in a manly way, and he deplored his connection with the Company.

Mr. POPE, Q.C., said it was impossible in a meeting of that kind for the Directors to enter into any defence they might have. He was sorry that Dr. Duncan had forgotten that an angry man was generally an unjust man, and before he talked about Directors disgorging he should have satisfied himself that they had put anything into their pockets to disgorge.

Mr. ABRAHAM denied that he had said anything against the personal honour of Lord Aberdare.

After further discussion, Dr. Squire, Mr. Pilling, Dr. Duncan, Sir Jas. Lawrence and Mr. Bond were appointed to act with the committee elected at the creditors' meeting. It was stated that there was some doubt whether Mr. Bond had consented to serve on the creditors' committee.

The following is an abstract of the summary of the statement of affairs of this Company at May 17, 1893, the date of the winding-up order, and the Official Receiver's observations thereon:—

After alluding to the proceedings in Court, before the winding-up order was made, the Official Receiver states that the business of the Company has been divided into two branches:—

(*a*) Electrical and general engineering and contracting, and dealing in electric goods.

(*b*) Dealing in patents, &c., in which connection the Company has been identified with the promotion of various other companies, which are referred to hereafter.

The Company's offices, branches, &c., are next set out, and these are followed by a recapitulation of the various Companies which Woodhouse and Rawson United (Limited) was established to amalgamate, which it is unnecessary here to set out. This is followed by a tabulated list of the persons who have constituted the Directorate of the Company from its formation, the date of their appointment, and the date of resignation. The table also gives the present share holding of these Directors, and the Directors' fees received. Sir Rawson W. Rawson, who joined the Board on August 5, 1889, received nearly £1,500 in Directors' fees, and has a holding of 70 Ordinary shares. Mr. F. L. Rawson received £932 Directors' fees, and claims to hold nearly 1,600 Ordinary shares and 4,350 Preference shares. The total amount of the present holdings of Directors is given by Mr. Stewart, the Official Receiver, as £4,500 in all.

The Official Receiver has examined the profit and loss account of Woodhouse and Rawson (Limited), on which a profit of £21,440 is represented to have been made for the year ending June 30, 1888, and discovers that a large portion of the profit arose by reason of the assumed value of various interests in other companies. So doubtful was the real profit that the auditors prepared a special report, the concluding paragraph of which is as follows:—"The accounts are in accordance with the books of the Company, but it is obviously impossible for us to be responsible for the net profit, having regard to the nature of the assets and the Company's interest in many trading concerns not yet fully developed, and without Stock Exchange quotations of their shares."

A balance-sheet of Woodhouse and Rawson (Limited), as at June 30, 1889, and a profit and loss account for the year ending that date, were duly prepared, the latter showing an apparent profit of £78,222. 3s. 6d.; the auditors do not appear to have been instructed to examine it until May of the succeeding year; their report is dated June 26, 1890, and the Official Receiver gathers therefrom that very grave doubts existed in their minds as to the reality of the profits, having regard to the sources (similar to those of the previous year) from which such profits were represented to be drawn.

The Official Receiver has not seen the accounts in the liquidation of Woodhouse and Rawson (Limited), which commenced in September, 1889, and, consequently, has at present no means of informing himself precisely to what extent the said profits have been realised; but he believes it is the fact that a large portion of them was illusory, and it may be necessary hereafter to apply for an inspection of the said accounts; in this connection Mr F. L. Rawson states that, although certain of the items treated as profit were not subsequently realised, the liquidators, on the other hand, received considerably more for their interest in the Elmore Companies than was taken credit for.

All the businesses taken over by Woodhouse and Rawson United (Limited) are stated by Mr. F. L. Rawson to have been profitable prior to the amalgamation, with the exception of the Woodhouse and Rawson Electric Manufacturing Company and the Woodhouse and Rawson Electric Contract and Maintenance Company.

A further tabular statement sets out the terms on which the various businesses taken over were acquired. £192,000 was paid for Woodhouse and Rawson (Limited), of which £93,278 was in cash; £15,000 for the Woodhouse and Rawson Electric Supply Company (Limited), (£2,500 in cash); £32,000 for the Woodhouse and Rawson Electric Manufacturing Company (Limited), (£9,000 cash); £6,000 for the Woodhouse and Rawson Electric Contract and Maintenance Company (Limited), (no cash); and £24,000 for C. L. Baker and Company (£5,000 cash), representing a total of £269,000, of which £109,778 was cash, £54,722 in Debentures, £42,820 in Ordinary shares, and £49,680 in Preference shares. The properties taken over were duly valued, and (including about 78 patents) £345,230 was the sum arrived at as the value of the various businesses, including £97,000 for goodwill, which amount appears to have been simply agreed.

The nominal capital of the United Company was originally £350,000, and was increased on February 2, 1891, to £550,000, divided into 50,000 Preference and 60,000 Ordinary shares of £5 each. The first prospectus, dated July 15th, 1889, states that "15,700 Ordinary and Preference shares have been applied for by the Directors and their friends, and will be allotted in full at par." The Official Receiver has been unable to verify this statement, except as regards about 12,000 shares, from the Company's records.

In November, 1889, the Directors issued a second prospectus, offering for subscription 10,000 Ordinary and 10,000 Preference shares at a premium of 5s. per share; also 400 debentures of £100 at a premium of £2 per debenture, being the unissued balance of the capital of the Company. This prospectus states that "The wisdom of the amalgamation is shown by the fact that already more business of a profitable character has been offered than the capital issued enables the Company to entertain, thus justifying the correctness of the view formed in fixing the amount of the Company's capital on its formation, and the Directors entertain with confidence the realisation of the prospects held out in the original prospectus."

In January, 1890, another prospectus was issued, offering for subscription 3,684 Ordinary and 6,866 Preference shares, at a premium of 5s. per share, and 289 debentures of £100 each, at a premium of £2 per debenture. This document states that "the prospectus, announcing the formation of the Company, was issued on July 15th last, since which time it has been exceedingly successful, and an interim dividend has just been paid for the period ending December 31, 1889, at the rate of 15 per cent. per annum on the Ordinary shares and 8 per cent. on the Preference shares in respect of profits realised since the formation of the Company. The prospects for the second half-year promise to be equally satisfactory, besides allowing for the carrying of a substantial portion of the profits to the reserve fund."

No further prospectus appears to have been issued until February, 1891, when, the nominal capital having been meanwhile increased, the Directors placed a further invitation before the public to subscribe for 20 000 Ordinary shares of £5 each, on which also it was stated that there was

Digitized by Google

"no present intention to call up more than £2. 10s. per share," 10,000 Preference shares of £5 each, and £100,000 Five and a-Half per Cent. Debenture Stock, redeemable in ten years at £105, or at an earlier date (but at the same premium), with the consent of two-thirds of the holders of the stock. This prospectus states that "the objects of the issue are to provide capital for the constantly increasing business of the Company, and to carry out various additional proposals, including a contract for the lighting of a portion of the City of Paris, and further to enable the Directors to pay off the balance of the £75,000 deposited [as a guarantee fund] with the Company, which they can now do on advantageous terms." The Company paid only one half-year's dividend after the issue of this prospectus.

On November 30, 1891, yet another prospectus was issued, with a view of obtaining subscriptions for 10,000 Ordinary and 13,000 Preference shares of £5 each, and £50,000 Five and a-Half per Cent. Debenture Stock. With regard to the Ordinary shares, it is again stated "that there is no present intention of calling up more than £2. 10s. per share." Representations are again made in this document as to the flourishing state of the Company's business. These various prospectuses are stated to have been drafted by Mr. F. L. Rawson, and settled by the Board of Directors; in addition to the issue of the prospectuses to the public, subscriptions for shares, &c., were invited by means of advertisements in the leading newspapers. When new shares were issued the subscribers were made to pay up to the same point as original shareholders.

The Official Receiver's document sets out the further businesses which were acquired by the Woodhouse and Rawson United Company, including Jensen's Bell business, for which £2,050 in cash was paid; Thorne's Tachometer Patent, price £450 cash and £500 Preference shares; Mr. Jacob Bohn's instrument business, price £1,000, £929. 10s. in cash and £70. 10s. still owing; Messrs. King, Masterman and Terry's business at Union Foundry, Kidsgrove, for which £36,600 was paid, £5,000 in cash, £25,000 in Six per Cent. Debentures, and a further cash payment of £6,500 to clear a mortgage on the works; and, finally, Sargeant's Electric and Steam Launch Works, for which £1,000 in cash was paid. The two latter undertakings were acquired on a report by the Woodhouse and Rawson Company's then Manager, Mr. George North.

This statement is followed by a summary of the printed balance-sheets and profit and loss accounts prepared by the Company from the date of formation to July, 1892. The Official Receiver points out that in the accounts to June, 1890, in the items "Salaries, &c," amounting to a total of £25,269, includes a sum of £13,775, with which Mr. F. L. Rawson was credited, being a commission of 25 per cent. which he was allowed in terms of his agreement with the Company in respect of surplus profits that remained after the payment of 15 per cent. dividend to the Ordinary shareholders. No portion of this amount was received by him in cash.

At the same date a profit of £37,235 was claimed for the promotion of the International Okonite Company (Limited), which the Official Receiver regards as a very doubtful item, seeing that the Woodhouse and Rawson United Company immediately afterwards subscribed for shares and debentures in the Okonite Company for a very large amount, and at the date of the winding-up order held securities to the amount of £33,721. 10s (estimated to produce £22,057). On this occasion an Employé pension fund was formed, to which the Company contributed £1,000. Having regard to the facts above mentioned, the Official Receiver points out that it must be matter for further consideration whether the Directors were justified in treating certain of these profits as earned and divisible; whether Mr. F. L. Rawson was entitled to be credited with the above sum of £13,775; and whether the whole facts of the case were fully before the shareholders when they consented to part with the Guarantee Fund previously mentioned. It is pointed out that the International Okonite Company was only registered in June, 1890, and that therefore its prospects could only have been conjectured when the large sum of £37,235 was included as a profit in the balance-sheet to June 30, 1890.

In the balance-sheet to July 31, 1891, the Dividend Guarantee Fund disappears. This alteration was effected at a meeting of shareholders held in January, when it was represented that the company had attained to such a flourishing state that the retention in this fund was not further necessary. "Sundry investments" set out in this balance-sheet amount to £119,338. 15s., consisting largely of Elmore, Okonite, Epstein, and Phœnix Trust Shares, and the profits of the company for the year include a sum of £14,975 appreciation on shares in the Phœnix Trust Company, £35,145 treated as profit on the promotion of the Epstein Accumulator Company, £2,000 for services rendered in the promotion of the Ward Electric Car Company, £1,112 assumed profit on the holding of the Company in the Sociedad Española, and £2,640 an assumed profit in respect of certain assets acquired by the taking over of the Kidsgrove Foundry; £500 was added on this occasion to the Employés pension fund. The accounts for this year will form the subject of further inquiry as to whether the Directors were justified in declaring dividends out of profits, which could only be "estimated" and were to a large degree unrealised. Nothwithstanding the alleged prosperity of the Company during this period, the Directors found it necessary to borrow largely at 6, 6½, and 7 per cent. interest, and immediately after the date of the balance-sheet, and between the period of the annual general meeting in the following November, further large sums had to be borrowed at 6 and 7½ per cent. interest. In November, 1891, money had to be borrowed and in some cases at very high rates of interest. The dividend of 8 per cent. on this occasion was the last dividend the Company paid.

In the accounts to July, 1892, "Special losses" are set out at £69,531, which includes £14,473 by the Edison-Swan Lamp action, £17,784 loss at the Kidsgrove Works, and £37,274 loss on trading, &c. In December, 1892, the auditors of the Company issued a circular to the shareholders, in which they state that the books of the Company had not been balanced, owing to the fact that the Directors had not employed a sufficiently competent book-keeper. Owing to the manner in which the books were kept it was impossible for the auditors to complete the audit, and they state that a large number of the vouchers were missing, and that of the "investments" of the Company at that date amounting to £109,413 10s., 34,150 shares in the Epstein Accumulator Company were held by the Chairman (Sir W. W. Rawson), and the Managing Director (Mr. F. L. Rawson) as security for undertakings given by them on behalf of the Woodhouse and Rawson United Company in respect of contracts, rent, &c. The total loss for the year to July 31, 1892, appears to have been £122,198, even supposing that the securities and the sundry debtors realised the amount taken credit for, and that the stock goods in transit and expenditure on contracts in hand (amounting to £123,120) realised their full value. The actual nett loss for this year amounted to £129,765.

These accounts were received with great dissatisfaction by the shareholders, and at a meeting on December 22, 1892, a consultative committee was appointed to investigate the Company's affairs, and have since reported very unfavourably thereon. The Official Receiver proceeds to point out that the energies of the Directors were chiefly devoted to the promotion of companies, and that it is open to question whether they were justified in so engaging themselves, having regard to the fact that the first prospectus only contemplated the carrying on of an industrial business; and as regards the payment of dividends, it is possible that some claim may rest upon the Directors for reimbursement.

The statement of affairs of the Company prepared by the which follows was filed on November 30, 1893. No reasons which the Official Receiver thinks adequate, have been assigned for the delay which has taken place in submitting this statement. The statement shows liabilities as regards creditors of £14,713. 9s. 2d., and assets estimated to produce £44,349 17s. 5d., or an estimated surplus, after meeting the liabilities of the Company (subject to cost of liquidation) of £29,636. 8s. 3d. There is no unpaid capital liable to be called up. As regards contributories there is a total deficiency (again subject to cost of liquidation) of £477,957. 16s. 2d. There are 1,303 creditors, 1,300 debtors, and 1,683 shareholders.

The Official Receiver states that Mr. F. L. Rawson's transactions with the Company have been somewhat extensive and varied, and Mr. Stewart is not disposed, on the evidence before him at present, to accept as owing to Mr. Rawson the sum of £117. 0s. 6d. as the balance on the various accounts. A full investigation, the Official Receiver states, will probably disclose Mr. Rawson as a debtor of the Company.

The Official Receiver's report concludes with a careful statement of the total liabilities and assets of the Company, and is followed by the views of the Directors and other officials as to the present value of the assets. It will be observed that the assets are so valued as to make the Company appear solvent as regards creditors and leaves an apparent surplus for shareholders, but the Receiver for the debenture holders, who is now conducting the business, does not concur in this, and believes that it is doubtful whether the assets would realise sufficient to pay off all the claims of the debenture holders. In conclusion, the Official Receiver states that the books of account appear to have been kept in a very imperfect manner, and do not exhibit with sufficient clearness the past operations or present position of the Company, and that when the Receiver and Manager went into possession in March, 1893, the books were discovered to have been unposted from the previous December, and therefore the accuracy of all the Official Receiver's figures cannot at present be verified. There are a number of matters into which the Official Receiver proposes to make further inquiry, and it is intended to apply for a public examination of certain of the Company's officials.

Elmore's French Patent Copper Depositing Company (Limited).

A meeting was held on Wednesday at the Holborn Restaurant of the debenture holders and secured creditors of this Company, to consider a scheme of arrangement between the Company and its creditors. Mr. C. J. Stewart, the Official Receiver and provisional liquidator, presided. It was explained that the object of the scheme was, first, to satisfy the claims of the debenture holders and creditors of the Company; and, secondly, to resuscitate the Company, so that the reversion of assets might belong to the shareholders. If the scheme were adopted, those present must distinctly understand that it was not a scheme recommended by the Official Receiver. The scheme was adopted with one dissentient.

A meeting of the unsecured creditors was afterwards held, the Official Receiver again presiding, and on the motion of Mr. John Heal, seconded by Mr. Shurmer, it was decided to approve the scheme, subject to the sanction of the Court.

The shareholders of the Company subsequently held a meeting, under the chairmanship of the Official Receiver, and after some discussion the scheme was approved, subject to the sanction of the Court.

Swan United Electric Light Company (Limited).

The annual general meeting of the shareholders of this Company was held at the Westminster Palace Hotel on Wednesday, Mr. J. S. Forbes presiding.

The SECRETARY (Mr. H. Charles Gover) having read the notice calling the meeting, the report and accounts were taken as read.

The CHAIRMAN said: I will begin by dealing with the balance-sheet and profit and loss account, because, in view of a possible contingency, it has had to be made up rather in the nature of a final balance of our affairs to September 30th. I have an apology to make. The meeting is called three weeks later than it was last year, for a reason which, I think, when you know it, you will regard as satisfactory. We promised at the last meeting that measures should be taken with a view of combining the

Digitized by Google

remnant of our business with the bulk of our investment in the Edison and Swan Company. The necessity of the running out of the patents, and the altered condition of things likely to arise when we are out of the baleful influence of protection, and are in the open air of free dealing, make it desirable that our affairs should be as compact as possible, and be managed as economically as possible. I think that all those reasons are well understood by the shareholders of both Companies, and during the interval the negotiations have proceeded between the Company and the Edison and Swan Company, and have now reached that stage at which, as far as we are concerned, our responsibility will end and that of the proprietors will begin. Briefly, What is the price which the Edison and Swan Company are to pay to the Swan shareholders for the remnant of their business not already included in the Edison and Swan Company? We thought the better plan was that two gentlemen interested in the Swan Company and two gentlemen interested in the Edison and Swan Company should have the necessary preliminary discussions, and should, if possible, arrive at some basis of agreement. That has been done. The matter is a good deal complicated by the relative position of the fully-paid shares and the partially-paid shares in the Swan Company, and therefore we asked Mr. Swan, who represents for the most part a holding in fully-paid shares, and Mr. Quilter, who represents more especially the partly-paid shares, to see what would be a fair method of dealing with the cake when you have got it to cut. Then, of course, we had to ascertain how big the cake was and the ingredients of which it would be composed, and whether it would be palatable. That involved another process. Sir John Lubbock, although not a Director of the Edison and Swan Company, was originally intimately connected with it, and was good enough, in conjunction with the Earl of Lichfield, a Director, to consider the question from the point of view of the purchasers. After rather prolonged negotiations a basis has been arrived at as regards not only what the Edison and Swan Company are prepared to give for this residuum, but how far the purchase price was to be divided between the fully-paid shares and those partially paid. It is rather too complicated to go into details, but it was not so easy to arrive at a conclusion; and the conclusion arrived at seems to be as equitable as is possible in a case where the factors are partly existing and partly problematical. Briefly, it is this: The Edison and Swan Company, in which we are interested to the extent of 60 per cent., agree to give £100,000 in the shape of a 4½ per cent. debenture stock, of course forming a first charge over their whole income. You yourselves, by that process, will put over your own heads £60,000 of 4½ per cent. debenture stock, and your partners in the Edison and Swan Company—who hold 40 per cent. of the interest—the original Edison Company, will put £40,000 over their heads. But dealing with the bargain it is to be remembered that £100,000 of debenture stock, of a first charge, as far as that amount goes, as against future risks and contingencies, is extremely safe-guarded compared with the rest of the capital, because, as you know, a debenture is a mortgage of the property, and the interest is cumulative, and assuming anything should arise to raise an issue between the two classes of capital it is quite clear that the one has a great advantage in respect to its priority, both for principal and interest over the other. As I shall have to present this matter, if it is approved, to the shareholders of both Companies, I have examined it, and being conversant with the difficulties of dealing with a positive factor in conjunction with a factor more or less impalpable and uncertain, I have arrived at the conclusion that it will be a very good bargain for both sides. First of all it will unite the two concerns, and secondly it will strengthen our hands as against the severe competition to which we are probably about to be subjected both in England and abroad, and it will effect certain economies which will be extremely advantageous to the united body. I will now proceed to the profit and loss account in order that I may explain how it is that it differs in some senses from preceding forms, and I will go to the credit side of the account first. The sales, less commissions and allowances, stand at £10,346, transfer fees and interest £646, the dividend on shares in the French Company £878, and the dividends on shares in the Edison and Swan Company £24,826. Now, I want you to observe the two next items: proportion of further dividends accruing to September 30, 1893, on the above shares, estimated at £6,000. That is brought in because the theory of this amalgamation is that it is to apply as from October 1st of this year. This Company, with its liabilities and income, &c., would be merged as from October 1st last into the accounts of the Edison and Swan Company, and that made it important to bring into the account an item which had not appeared before. We are creditors upon the Edison and Swan Company from June 30th to September 30th for dividend, and when the accounts are published of the other Company we shall find, I suppose, that that proportion of further dividends is an asset of this Company. Treating this as what I call a winding-up balance, it was necessary to bring that £6,000 into the accounts in order that there might be no asset when fusion took place, if it does take place, belonging to us which should not be kept by us and not form part of the assets to be transferred on the amalgamation taking place. The next item is "dividends received and due on shares in the National Telephone Company (Limited)." We had a considerable amount invested in Consols paying a very miserable rate of interest, and we thought it wise, when the price of those Consols reached a figure which got us out without a loss, to sell out and put the money into some undertaking which at all events would pay some reasonable dividend. The opportunity offered at that time to take shares which were about to be issued by the National Telephone Company, and as Mr. Quilter and myself both knew something of the position of that Company, we persuaded our colleagues to put the money into that as an investment which will return a reasonable dividend. It has paid 5 per cent. For the £25,000 invested in that Company, we have got 5 per cent. instead of 2¾ per cent. That will account for the item of transfer fees and interest showing a diminution, as against the corresponding figure in the previous year, when it was £1,168. You have to add those two together, and the result of the operation is shown, if you do that, to be £1,700 instead of £1,168. I do not think I need dwell more on this side of the profit and loss account, except to bring you down to the item of "balance of suspense accounts — law costs." Unfortunately, ever since the initiation of the lamp business, we have been more or less in litigation—patent fights, &c., and solicitors have a very bad habit of not sending in accounts to date, so there is always a running account. The thing was very complicated from the fact that the Edison and Swan Company and the Swan Company in much of this litigation were partners, and it has only been recently, upon a final account being delivered from the solicitors of these law costs, extending over several years, both in this country and Germany, and the proper attribution of the amount to the two Companies, that we have been able to state the accounts properly as between them; and the agreeable position in which we found ourselves was this—that in our former accounts, as presented from year to year, the aggregation of over payments amounted to £2,300, part of which was revenue and part capital, and, therefore, we have credited the profit and loss account with a balance of £800 over paid by us in former years from revenue. If you carry your eye down the balance-sheet you will see that the costs represented by patent rights, &c., £328,563, have been diminished by £1,500, the amount over estimated for legal charges paid out of capital. We have now, therefore, our account clear of that item, and it amounts to this—that in the aggregate sums paid by the two Companies we have debited ourselves with £2,300 more than was fairly attributable to us, and we have now got that money back. With regard to the item of stock on September 30th last, it represents the value of the stock of lamps, platinum, and other apparatus in store at the end of our year. If you carry your eye up to the top of the debit side of the profit and loss account you will find that we began the year with a stock amounting to £14,654. It is quite certain that in this lamp business stock in hand must always form a very serious item in the balance-sheet, and one which may well be the subject of a good deal of anxiety. I have had to explain before that, having a large business in lamps, it cannot be carried on without an enormous number of various types of lamps in stock, and the number of different types and depots, agencies, &c., that we have to maintain involves a very large amount of money locked up. I suppose that would be one of the difficulties of a small manufacturer. This £8,507 only represents the stock we have at Kalk, in Germany, where our business is now confined exclusively to Germany. By agreement with the French Company we are precluded from selling lamps in any other part of Europe than Germany, and it takes £8,500 of stock in lamps to keep our customers going, who from day to day want this or that type of article. In Great Britain it is, of course, a much larger amount. It is proportioned, in fact, to the amount of lamps sold in the course of a year, and the proportion sold in Germany is very much smaller than that sold in Great Britain. However, it is satisfactory to see that during the year to September 30th we have been able to work the stock down from £14,654 to £8,507. That has been done partly by disposing of it and partly by writing down the value of it in the books as carried over. A certain amount must therefore be written off for depreciation. I think I can present the accounts now as being in a most wholesome shape, and as showing if we do go into partnership with the Edison and Swan Company what we reserve for ourselves in the nature of profits already accrued but not yet announced in the accounts of the Edison and Swan Company. The purchases, the salaries, the wages, and expenses at the factory are all set out, and the balance is then given of £28,877. That balance is made up largely, as you see, of the contribution by way of dividend on the shares held by this Company in the Edison and Swan Company. That dividend shows a falling off of £12,200, as compared with the preceding year. I am afraid complications arise from people having their money in two pockets. They forget the relations between one pocket and another. During the last few years the Edison and Swan Company paid on the face of the accounts very large dividends, but these were made up of two elements—the 7 per cent. to which the A shares were entitled out of the profits of the particular year, and the payment in respect of that 7 per cent. during the years when it was not earned; and as long as those accumulations of between £130,000 and £140,000 were being paid off, it meant a very large dividend on the face of the accounts. Last year, for the first time, we were enabled to wipe out the balance standing to the debit of that arrear, and to carry over a considerable sum which had to be distributed between the Edison and Swan A and B shareholders; but the dividend, under those circumstances, distributed was 10 per cent., and in comparison with the dividend in the preceding year, shows £12,000 less than in 1892, when the item of unredeemed arrears was so considerably greater. Now, going to the balance sheet itself, the share capital stands exactly as it did. The item of sundry creditors is £2,943. That item last year was £5,000, and now we have managed to pay cash and reduce it to about £3,000 in round figures. The balance from previous account is £6,825, and the balance on September 30th last, brought down from the profit and loss account, is £28,877, making together £35,702, available. We paid a dividend for the six months ended March, 1893, at the rate of 5 per cent. per annum, which absorbed £9,376, and what we propose to pay to-day is enough to bring up the dividend to 7½ per cent. for the year. That will take £18,013 and leave £8,312 to carry forward. We have suggested that because the £6,000 proportion of further dividend accrued to September 30th last on our Edison and Swan shares, although pretty safe, is not yet in our pockets. It will not be ours until the accounts of the Edison and Swan Company are made up. That is why we feel that we should carry forward now £8,312, instead of £6,824, as we did last time. On the other side of the balance-sheet there is the value of what our capital is invested in:—Cost of patent rights, represented by shares in Edison and Swan United Electric Light Company (Limited), with £208,478 paid; shares in La Compagnie Générale des Lampes Incandescentes with £30,489. 8s. 3d. paid; patents held by the Company for Germany, &c., as per last balance-sheet, £328,563. That is reduced by the £1,500 that I have mentioned overpaid on account of law

Digitized by Google

charges. That brings the item down to £327,063. In order to impound that £6,000 accrued dividend on our Edison and Swan shares to which I have referred, and keep it in our pocket instead of having to transfer it in the event of this arrangement coming off, we show it in the balance-sheet. Then there is the outlay on factory, plant, &c., £1,570; and sundry debtors figure for £33,772. That is very satisfactory when you look at the item on the other side of the balance-sheet of sundry creditors, which stands in round figures at £3,000. That shows a surplus of debtors, all good, over creditors of £30,000. That is explained by the fact that we cannot afford to let our money lie idle, and we are obliged to invest it. We have invested £20,000 on Stock Exchange loans, and instead of getting 1 per cent. or 1½ per cent., we get 2 per cent. or 2½ per cent. We have also lent the Edison Company £10,000, and those two sums mop up the £30,000. With regard to our investment of £25,000 in the Third Preference shares of the National Telephone Company, those shares now stand at a modest premium, but, although fully aware of the danger of prophesying, if it turns out wrong, I have no hesitation in saying that these shares are worth a great deal more than their present premium. Cash on deposit and in hand brings me down to the final entry. If you had before you the balance-sheet of the preceding year you would have seen that we have got rid of £29,000 of Consols and £5,000 of Prussian Consols. We got out of the Prussian Consols at a profit, and out of the other Consols at about their cost price, and the money is now in your pockets, partly in the shape of cash, and substantially in the shape of this investment in the National Telephone Company. I will now conclude by moving—

"*That the report and accounts for the year ended September 30, 1893, be received and adopted.*"

The DEPUTY-CHAIRMAN (Mr. Quilter, M.P.) seconded the motion.

Col. STROUD stated that in the two Companies the assets shown for patent rights amounted to £700,000. Those patent rights, however, as he understood, ceased to have any effect on November 11th, and did not represent a farthing of value. In their own case the proportion roughly was about £300,000. Would it not be better, as that asset was practically not worth a penny, as he understood it, to expunge it, and show only any real assets that they possessed?

The CHAIRMAN: The two sets of accounts show a discrepancy. The capital of the Swan Company was shown in the balance-sheet as £375,000, and the capital of the Edison and Swan Company was shown in their balance-sheet at about £350,000. Of the £350,000 standing in the balance-sheet of the Swan United Company, as shown on the credit side of the balance-sheet, they had £208,000 in shares of the Edison and Swan Company, and £30,500 in shares of the French Company.

Col. STROUD said that there were other assets that were valuable, but he considered that it would be better to expunge those assets that were simply in the air and to show only assets that were real and substantial.

The CHAIRMAN said that if the agreement in question were carried out the whole of the capital of the Swan United Company, now shown in the balance-sheet, £375,000 would disappear. The capital of the amalgamated undertaking would stand at £350,000, *plus* the £100,000 to be paid to the Swan Company as mentioned. The amalgamated capital would, therefore, not be £700,000, but £450,000. What this Company had got now was the amount of capital invested in the whole business, including some other advantages, the £30,000 odd in the French Company, and the fact that they would be enabled on the expiration of the agreement with the French Company at the end of next year to remove the restriction for selling lamps all over Europe. By that agreement their sale of lamps was now confined to Germany. He was not able to say at present that it would be the case, but he thought it was quite on the cards that their partners of the French Company would see that it would be advantageous for them to remove the restriction in question. With regard to the Edison and Swan Company, they were not free to export lamps from Great Britain.

Col. STROUD asked whether the Edison and Swan Company's patent held good or whether any one could infringe it.

The CHAIRMAN stated that the lamp patents were gone, and for the £450,000 which he had mentioned they would have their lamp business not only in Great Britain but in all Europe and the world, because, the two Companies being together, the bar of exportation would be removed. The question was, was the £450,000 a sum that was likely to be covered?

Col. STROUD said that, with all deference, he thought not.

The CHAIRMAN said that the Directors thought it would be, but he was not going to give any pledge on the point. They had often said that the whole policy of the Company was built up on the vital fact that the protected period would end at a given date, and therefore their business was first of all to exercise the opportunity of protection to turn out the most efficient article. They had a monopoly of all the scientific information that came up during those years. They had had that advantage, they possessed the best factory in the world, and they had not limited themselves to the lamp business.

Col. STROUD stated that the Germans were at the present time importing lamps which he could buy at a shilling. He had made inquiries on the subject, and he heard that the Edison and Swan lamp was so superior at the present time that the vendors did not like to quote any other lamp.

The CHAIRMAN stated that they were perfectly well aware of the quality of other lamps that had been produced, because they had bought and tested them. He had not yet discovered that they made lamps in Germany cheaper than we could, although it was perfectly true that they had advantages in Germany which we had not here. They had been playing off their factory in Germany against their factory in London, and they found that the result in London was rather more satisfactory than it was in Germany. The matter turned on quantities. With regard to the quality of the lamp, Mr. Edison had a great name, and they had under their arrangement the opportunity of obliging their customer with any lamp—the Edison or the Swan. Any customer of theirs could have an Edison lamp made in New York at the same price as he had a Swan lamp made for in London; and the Edison lamp had disappeared, although, possibly, it would come back again. With regard to German lamps, he had no doubt that a great many of them would be sold in England at a very low price. The large stocks held in Germany could not be held without depreciation; and, as a matter of fact, they knew that all the refuse stock in Germany had been bought by speculators, and would be sold here as first-class lamps. When it was a question of an efficient lamp, he certainly thought they could hold their own against their German friends. What they hoped to do was to make up for the diminished profit on the limited quantity of lamps they had made during the protected period by the manufacture of an enormously increased number of lamps, which, though sold at a lower price per lamp, would make up for the difference in the profit. They had found as they went along that the lamp was not the only element to consider; there was the installation business—the holders, the switches, the fittings, and things of that sort, in connection with which they had some extremely valuable patents, which had several years to run. They had licensed many of the leading firms of manufacturers, who paid the Company a royalty. Their profit in future years would not depend exclusively on the lamp. They had reduced the price of the lamp to a nominal 1s. 9d. They gave a trade discount of 12½ per cent., according to quantity; and to large consumers—those who took 5,000, 10,000, or 20,000 lamps, the net price was only 1s. 5d. Concurrently with the enormous expansion now going on in electric lighting, their speculation was that *qua* the lamp, they would multiply the production enormously, and *qua* the other things, they had a business which, in the nature of it, must also be profitable.

Mr. F. W. REYNOLDS said he desired to confirm the remarks made by the Chairman. It appeared to him that when they offered an Edison lamp or a Swan lamp they would be able to command a much higher price. They had had 14 years' experience, and the benefit of Mr. Swan's constant experiments; and he (the speaker) had no doubt that Mr. Swan's name would insure the continuance of the business. He desired to know how they would stand in regard to the liability of 30s. a share on their shares if the proposed amalgamation was carried out.

The CHAIRMAN said that there would be, under the arrangement, a wiping-out of capital; but this was of no consequence, because they would retain their profit-earning power, and whether the capital was more or less, the amount available for dividend would be the same. With regard to the liability of 30s. a share upon the Swan shares, it represented a great deal more than the £2 a share on the shares in the Edison and Swan Company, and to the extent of the difference they would escape this liability. He did not see himself, however, that in either one or other case there was any immediate fear of new capital being required. In answer to a question of Col. Stroud, the Chairman added that the competition, prospective and potent, up to the present time since the termination of the protected period was not at all appreciable. He believed they were quite safe in the transition period. He afterwards called attention to a circular regarding the proposed amalgamation which had been issued by Mr. Quilter and Mr. Swan to the fully-paid shareholders, and stated that up to the present, out of 19,750 shares, assents to the scheme had been received from holders of 14,896; the holders of 4,854 had not responded. On the scheme being carried through application would be made to the Stock Exchange for a quotation. He would present the plan in due course to a meeting of an aggregate body of the shareholders.

The resolution was then put to the meeting, and carried unanimously.

The CHAIRMAN afterwards proposed the following resolution:—

"*That in addition to the £9,376. 15s. 9d. already distributed in respect of the six months ended March 31, 1893, a further sum of £18,012. 19s. be divided, free of income-tax, to be distributed in accordance with the provisions of Clause 77 of the Articles of Association, making a total distribution for the year of £27,389. 14s. 9d., being at the rate of 10 per cent. for the half-year, and making 7½ per cent. for the year ended September 30, 1893.*"

Mr. QUILTER seconded the motion.

The CHAIRMAN put the resolution, which was carried, and he stated that the warrants would be received by them on the 23rd inst.

Mr. Quilter and Major S. Flood Page were re-elected as Directors, and Messrs. Welton, Jones and Co. as auditors.

A vote of thanks to the Chairman and Directors terminated the proceedings.

The report above referred to is as follows:—

The profit and loss account for the year shows a credit balance of £28,877. 9s. 6d., which, together with £6,824. 17s. 9d. brought forward from the last account, leaves disposable the sum of £35,702. 7s. 3d. An interim dividend in respect to the first half of the year, amounting to £9,376. 15s. 9d., has already been paid. The Board proposes that a further sum of £18,012. 19s. be divided (free of income-tax), and that £8,312. 12s. 6d. be carried forward. This is equivalent to 7½ per cent. per annum on the partly-paid, and of rather less than 7½ per cent. upon the fully-paid, shares. The shareholders are reminded that Messrs. Quilter and Swan were deputed to meet Sir John Lubbock and the Earl of Lichfield, acting for the Edison and Swan United Company, with a view of suggesting a basis on which an amalgamation with this Company could be effected. The basis having been generally agreed upon, it became necessary to ascertain in the first instance whether the fully paid-up shareholders of this Company are prepared to accept the terms. Messrs. Quilter and Swan have now by circular addressed each fully-paid shareholder with a view of ascertaining whether they approve of the amalgamation of the companies on the arranged basis. As soon as this has been ascertained the matter will be brought before the partly-paid shareholders, and, if approved, a general meeting will be called to give effect thereto.

The Exploration Company (Limited).

The annual meeting of this Company took place on Tuesday at the Cannon-street Hotel, under the presidency of Sir Horace B. T. Farquhar, Bart.

The CHAIRMAN, in proposing the adoption of the report, said: Gentlemen, the reason why a long interval has occurred since our last meeting is that we hoped and wished to announce to you that the issue of the Central London Railway had been made. But that was found impossible, in the first place, because the approval by the Commissioners of Sewers of the City of London of the plans for a central city station and public subways at the Bank was only obtained in June, and, secondly, because since then financial conditions in London have been so distinctly unfavourable that it has been deemed prudent to defer this issue. You will have seen that we recommend the payment of about £12,000 in dividends. If you endorse our recommendation, the Exploration Company will then have distributed altogether £67,600 in dividends on a paid-up capital of £30,000. The first business mentioned in the report is the Central London Railway, the most important enterprise with which the Exploration Company has hitherto been connected, and one which we trust to bring to a successful termination. The line meets with a great want of the people of London, and from all the close study to which we have subjected it, we are confident that it will be enormously patronised. A heavy traffic is waiting for it, and the working by electricity should be cheap — cheaper than by steam. These two factors make us feel assured that this line will be a large and lasting dividend-earner. We have, in fact, the very highest opinion of its earning capacity. Whenever, in great cities, means of quick transit have been afforded directly on the established lines of traffic—and not at some distance from them—the financial results have been brilliant. The engineers state from actual experience that the construction will not take long; the streets will not be opened up nor the traffic stopped. The authorised capital is £2.850,000 in shares, and £950,000 in debentures, which, we believe, will be ample for all purposes. We consider it of mutual advantage to have obtained of the City authorities the approval of our plans for dealing with the central part of London, between the Royal Exchange, the Bank of England, and the Mansion House. The vehicular traffic at that well-known centre has, as you know, to be stopped constantly. The City authorities have to face the daily problem of regulating the overgrown traffic—an ever-increasing difficulty. The proposed subways will it is hoped, remedy this congestion; they will be made and maintained by the railway company, but open to the public. This arrangement will be of material benefit to the City, while, on the other hand, the right of the railway company to construct its principal City station under that most desirable place is confirmed. and the station becomes accessible from all sides. The Chairman afterwards referred with satisfaction to the important interest which the Company had in deep-level mining in South Africa.

Mr. F. A. LUCAS seconded the motion, which was adopted, and the dividends recommended were afterwards approved

---

The Telegraph in South Africa.

The Duke of Abercorn presided over the third annual meeting of the British South Africa Company, which was held on Tuesday at the Cannon-street Hotel.

In their report the Directors said:—"The amount expended in telegraph construction during the year is £392. 7s. 3d., making the total cost of the Company's line to March 31st, 1893, £93,201. 1s. 2d. The whole line from Mafeking to Salisbury, 819 miles in length, is working well; but it has been found necessary to renew a large number of the wooden poles in the Nuanetsi-Salisbury section owing to the ravages of the white ant. The increase in the cost of maintenance from £2,137. 15s. 1d. last year to £4,242. 16s. 2d. this year is largely due to this cause. It is expected that the expenses of the Company's telegraph service will be reduced next year, as arrangements have recently been made with the Postmaster-General of the Cape Colony for the management and superintendence of the line. He now controls the telegraph clerks and undertakes all technical management, while the expenditure remains under the control of the Company's Managing Director in South Africa. This arrangement is a satisfactory one for the Company. It will be remembered that Mr. Rhodes, at the general meeting last year, brought forward his scheme for a transcontinental telegraph. Since that date, with the support and authority of this Company, a Company, called "The African Transcontinental Telegraph Company, Limited," has been formed, and sufficient material has been shipped (and is now in Africa) to extend the telegraph system from Salisbury to Zomba in Nyasaland. The British South Africa Company cannot fail to benefit largely by this extension. Although erected by an independent company the new line will not only increase the traffic over the Chartered Company's own line, but will connect the latter Company's field of operations North and South of the Zambesi.

The CHAIRMAN, in the course of his remarks in moving the adoption of the report—which was agreed to—said: Mr. Rhodes, in his speech last year, fully explained his views respecting a transcontinental telegraph. A Company has since been incorporated under the title of the African Transcontinental Telegraph Company (Limited), with the cordial support and authority of your Directors. We have not, however, thought it expedient on behalf of the Company to subscribe for shares or render any purely financial assistance. You all individually have had an opportunity of subscribing for shares, as have the shareholders in other companies with which Mr. Rhodes is associated.

NEW COMPANIES, STATUTORY RETURNS, &c.

ACME AND IMMISCH ELECTRIC WORKS (LIMITED).—This Company was registered on December 16, 1893, with a nominal capital of £25,000, divided into 20,000 Ordinary and 5,000 Preference shares of £1 each, to acquire the undertakings, businesses, and assets of the Acme Works, of Chalk Farm, London, N.W., and of the General Electric Power and Traction Company (Limited), of Kentish Town, London, N.W., with a view to such acquisition to enter into and to carry into effect the following agreements:—(1) Dated August 15, 1893, between Francis Teague and Russell Aitken of the first part, John A. Iliffe of the second part, and James Renwick (on behalf of the new Company) of the third part; (2) with the General Electric Power and Traction Company (Limited); and (3) with the Electric Construction Company (Limited), to generate, accumulate, distribute, and supply electricity for the purposes of light, heat, motive power, or otherwise, and to carry on the business of electrical and mechanical engineers, electricians, and manufacturers of and dealers in machinery, stores, appliances, and apparatus of every description applicable for or in connection with the supply or use of electricity. The subscribers are:—

Sir Henry C. Mance, C.I.E.	10	Pref. Shares.
Moritz Immisch	10	„
William Bullock	10	„
James Gray	10	„
Emile Garcke	10	„
Thomas Smith	10	„
James Renwick	10	„

The first Directors are to be appointed by the signatories above.

NEW PANULCILLO (LIMITED).—This Company was registered on December 16th, with a capital of £50,000, in £1 shares, to enter into and carry into effect an agreement, dated December 15, 1893, and made between the Panulcillo Copper Company (Limited) and Sir John Pender, G.C.M.G., M.P., Francis J. Johnston and Frank W. Bond (the liquidators of the said Company), and George Mountier (for this Company), whereby this Company purchases the copper mines and smelting works, situate at Panu'cillo, in the Province of Coquimbo, Chili, and to carry on the business of raising, crushing, smelting, washing, reducing, amalgamating, working and winning ores, metals, minerals, &c. The number of Directors is not to be less than three nor more than seven. The first are:—Sir John Pender, Francis J. Johnston, J. Denison Pender and R. S. Archbold.

"LIGHTNING" (LIMITED).—The annual return of this Company, made up to December 8th, has been filed. The nominal capital is £3,000, divided into 2,400 Ordinary and 600 Founders' shares of £1 each. All of these have been taken up, and 300 Founders' shares have been issued as fully paid. Upon 1,815 Ordinary and 226 Founders' shares the full amount has been called, and upon the remaining 585 Ordinary and 74 Founders' shares a call of 5s. per share has been made. The calls paid amount to £2,205. 15s.

MATHER AND PLATT (LIMITED).—The annual return of this Company made up to November 4th has been filed, when 15,000 out of a total of 20,000 £10 shares were taken up. Upon these shares a call of £9 per share has been made, resulting in the payment of £135,000.

NATIONAL COMPANY FOR THE DISTRIBUTION OF ELECTRICITY BY SECONDARY GENERATORS (LIMITED).—The annual return of this Company made up to November 1st has been filed. The nominal capital is £500,000 divided into 3,000 Preferred and 47,000 Ordinary shares of £10 each; 2,669 Preferred and 20,000 Ordinary have been taken up and allotted, of which 1,000 of the former class and all of the latter have been issued as fully paid. Upon the remaining 1,669 Preference shares a call of £10 per share has been made, resulting in the payment of £17,690.

CITY NOTES, &c.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—The coupons of this Company's Four per Cent. Mortgage Debentures, to bearer, due on January 1st, will be paid on and after that date at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, London, E.C. Warrants for interest on the registered debentures will be sent out on the 30th inst.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended December 17th were £905, as against £918 for the corresponding period of last year, being a decrease of £13. The total receipts for the half-year amount to £20,037, as against £19,894 for the corresponding period of 1892, an increase of £143.

DEATH OF MR. W. W. DUNCAN.—Mr. William Wallace Duncan, whose name is well known in connection with "Duncan's Tramway Manual," died in London, last week, after a long illness.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—Notice is given that the first call of £2 per share on the second issue of Preference shares in this Company is payable on January 9th next.

GREAT NORTHERN TELEGRAPH COMPANY.—The coupons falling due on this Company's shares on January 1st will be paid at the office of Messrs. C. J. Hambro and Sons, 70, Old Broad-street, E.C., where lists may be obtained. Coupons must be left three clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ending December 15th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £3,215.

Digitized by Google

WEST COAST OF AMERICA TELEGRAPH COMPANY.—This Company announce that the coupons due on December 31st on the Company's debentures will be paid by Messrs. Barclay and Co., bankers, London, E.C., and that coupons should be left two clear days for examination.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ended December 15th were £2,692, as compared with £2,510 for the corresponding period of last year. The receipts for August estimated at £3,587, realised £3,608.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 815.—Vol. XXXII. FRIDAY, DECEMBER 29, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

In our last issue we published some data relating to the working of the Cologne municipal central station, and called attention to them in an editorial note, thinking, with Mr. Crompton, that they were "interesting as showing the best figures that have as yet been obtained in Germany." Mr. Crompton, however, in a letter which will be found in our Correspondence columns this week, is evidently inclined to think that we wished to draw invidious comparisons, and award the palm for good engineering and careful central station management to the Germans. The English figures quoted were merely made use of so as to give an idea of the relative total costs of generation per unit in London and in Cologne, and we are glad to find that whilst Cologne beats London, Bradford and Liverpool redress the balance.

There are, however, two completely different aspects to this burning question of coal consumed per unit delivered and total cost of generating a kilowatt-hour. The shareholder of a company or a potential rival concern merely looks at the difference between the selling price and the total cost of manufacture; the one with a view to dividends, the other with a view to cutting-in; in neither case is the relative importance of the various items that go to make up the total cost of supreme importance; the shareholder, indeed, does not care one jot how it comes about that a commodity is manufactured at threepence and a fraction, so long as its selling price leaves a sufficient margin of profit. On the other hand, if anyone is bold enough to set out on the task of appraising the engineering and management of a number of central stations running under a variety of conditions, numerous factors have to be taken into account before even a convenient approximation of the truth can be arrived at. For instance, Mr. Crompton states that coal at Cologne is about 11s. 6d. per ton, and that 11·8lb. are used per unit, whilst at Kensington the figures are respectively 20s. 6d. and 5·8; but until we know the calorific values of the two fuels, it would be somewhat premature to argue that fuel at Cologne was really cheap, or to imply that the large consumption was due either to the inherent defects of the system adopted, or of the plant employed, or to the lack of experience and care of the *personnel*.

The discussion on action and reaction which appears in our Correspondence columns arises out of an ancient paradox. Paradoxes might form an interesting study from the point of view of pitfalls in science, into which generation after generation of students stumble. We are inclined to doubt that the tendency of different minds thus to trip at the same spot is due to some mental defect, but rather that something is wrong with our method of teaching, of definition, or of nomenclature. As regards teaching, a distinction has too artificially been kept between statics and dynamics. In statics we are told that two equal and opposite forces balance one another, there is no motion, and there is therefore equilibrium. By a false process of reasoning it appears that whenever there are two equal and opposite forces there can be no motion, and further, that if there be motion, it must be due to a superfluous force. This paradox sometimes takes the form of a horse and cart connected by traces. It is argued that the forward pull of the horse on the trace must be greater than the backward pull of the cart on the trace, else there would be no motion. If this were the case, spring balances placed at the ends of the traces would show different forces, and we presume that advocates of this view would admit that the difference between the forces—that is, the resultant force—multiplied by the distance over which the cart moved in a second, would give the amount of work done by the horse. Or, as Prof. V. Boys put it at a recent meeting of the Physical Society—if a chain were used the stresses would differ on different links. As a matter of fact, the horse pulls the cart with precisely the same force that the cart pulls back on the horse. No work is expended in doing this. The whole of the force exerted by the horse, multiplied by the distance traversed in unit time, assuming the velocity to be constant, gives the work done on friction or against gravity.

Local conditions being so widely different, it would be useless to compare the American Institute of Electrical Engineers with the English Institution of Electrical Engineers, but the last number of the "Transactions" of the former body gives an analysis of the result of election of its members which is perhaps worth noting in connection with our leading article of last week. Five applications for transfer were reconsidered, three were approved, and two were disapproved. Twenty-six new applications for transfer were considered, of these thirteen were "laid over for further consideration," ten were approved, and five were disapproved. The names of candidates are printed in the "Transactions," 'endorsed" by three members each, "one month in advance of action by Council," so that if any objection be raised to

Digitized by Google

proposed candidates members will have one month to file that objection to the secretary.

The three examples which we have selected for publication from Prof. E. L. Nichols's paper, and which will be found in another column, serve to indicate the wide field of usefulness of a wire heated by an electric current as a laboratory instrument, especially when combined with an apparatus for measuring temperature by means of electrical resistance. Both the readiness with which the temperature may be evenly distributed and gradually varied or adjusted at will, and the high degree of exactness in calibration, render these methods of considerable value in research work. In regard to the method adopted in the first-named experiment, we may remark that the temperature measurements being only relative, there was no need to assume any difference between the temperature of the coil and that of the substance which it enshrouded. But in more exact work, a thermometer might be inserted in the mass of the substance under test. Uniform temperature along the length of the test bar would require that the heating wire should be wound to an accurately constant pitch, and that the ends of the heating coil should project some distance beyond the ends of the test bar. This latter should also be arranged horizontally, and the irregular effects of convection currents should be prevented by suitable screens.

The Bimetallic Dynamo Company.—A company with this title and a capital of £10,000 has been formed in Paris to work the Reignier-Parrot patents.

Blackpool.—The Blackpool Tramway is being temporarily worked by horses. Mr. T. Parker and Mr. Holroyd Smith have both been engaged to inspect the line and plant, and to report thereon to the Town Council.

Governing Arrangements of Engines.—A special course of three lectures on this subject will be given at Finsbury Technical College by Mr. R. G. Blaine, Assoc.M.Inst.C.E., on Thursday evenings, from 7.30 to 8.30, commencing Thursday, January 18th.

Licensed Wiremen.—The New York Board of Fire Underwriters have, says the *Electrical Engineer* of New York, passed a resolution asking Governor Flower to have a law passed requiring persons desiring to do electric light wiring to pass an examination and to get a licence just as engineers have to.

Telephoning on Railways.—There are several instances in the United States where the telephone has superseded the telegraph in railway work. The latest case is in Indiana, where the Elkhart and Western Railway Company has erected a telephone line between Elkhart and Mishawaka in place of the telegraph.

The Anglo-American Telegraph Company and the Compagnie du Télégraphe de Paris à New York.—The action brought by the Anglo-American Telegraph Company against the Compagnie du Télégraphe de Paris à New York, which has been for so long before the Courts, was down for hearing before the Cour d'Appel de la Seine on Wednesday last.

Explosion at Glasgow.—Between 11 and 12 o'clock last Wednesday night an explosion occurred at the corner of Renfield and St. Vincent-streets, Glasgow. The accident is said to be due to a spark from one of the street cables igniting some gas which had escaped from a street pipe. The explosion resulted in two manholes being blown out. No one was injured.

The Telephone in Scotland.—The subscribers in the Scottish district of the National Telephone Company now amount to 10,167, being an increase of 1,143 over last year. The mileage of the Company in the district is 14,800, being an increase of 1,500 miles. The total number of conversations passing through the Company's system in Scotland is 29,000,000 in the year, being an increase of 11,000,000.

Massage and Electrical Resistance.—A singular property of massage is noticed by Dr. A. S. Eccles, who has discovered, says the *Electrical Review* of New York, that it indisputably decreases in a marked degree the resistance of the skin to the passage of electric currents. In this way the number of cells necessary in order to pass a given quantity of current through the skin, in cataphoric and other treatment, can be reduced.

Research Scholarship. — Mr. William Cecil Dampier Whetham, M.A., Fellow of Trinity College, Cambridge, has been elected to the Clerk Maxwell studentship in experimental physics. The student is required to devote himself, under the direction of the Cavendish Professor, to original research in experimental physics within the University. The studentship is tenable for three years, and its annual value is about £190.

Overhead Wires and Fire Escapes.—A somewhat serious fire recently occurred in Eliot-street, Boston, U.S.A., just at a point where there is a very thick network of overhead electric wires. While the firemen were handling one of the aerial ladders it came in contact with the wires, with the result that several of the firemen received severe shocks. This experience has stirred up the fire underwriters and fire commissioners to the point of demanding, for the twentieth time, that all wires shall be placed underground.

The Telephone in Germany.—According to the *Zeitschrift für Electrotechnik* the number of telephone stations in Germany, which was only 1,504 in 1881, had increased at the beginning of this year to 63,558, of which Berlin had no fewer than 17,424, with over 20,400 miles of lines. The inter-urban telephonic service is also increasing very rapidly, and there were at the beginning of the year 310 long-distance telephones, with 14,280 miles of lines, the longest direct line being that between Berlin and Breslau, which is nearly 200 miles.

The St. James and Pall Mall Electric Light Company.—We learn that complaints have been made to the St. James Vestry that scalding water and steam have been turned into the sewer, *presumably* by the St. James and Pall Mall Electric Light Company, and a certificate has been received from ten inhabitants that offensive effluvia are emitted from the chimney shaft of the generating station in Mason's-yard. Whether the Vestry will take any action or not depends upon what report their solicitors may make upon the papers submitted to them.

The Académie des Sciences Prizes.—At the annual general meeting of the Académie des Sciences, on December 18th, the La Caze physiological prize was awarded to M. d'Arsonval for his researches on animal heat and electricity, and the Gaston Planté prize was awarded to M. Blondlot, professor at the Nancy University. M. Blondlot has devoted his time of late to the study of Hertzian oscillations. In the department of electrical research the Gaston Planté prize will be awarded in 1895 for an invention or an important work in the province of electricity.

Cable Interruptions and Repairs:

	Date of Interruption.	Date of Repair.
Jamaica-Colon	November 25th.	December 26th.
Kotonou-Accra	December 4th.	December 27th.
Cayenne-Paramaribo	October 25th.	—
Cayenne-Vizeu	November 25th.	—
Lagos-Brass	December 4th.	—
San Domingo-Martinique	December 10th.	—
Haiphong-Hongkong	December 11th.	—
Garachico-Santa Cruz de Palma	December 27th.	—

Madrid.—The two large electrical companies in Madrid, which, so far, have kept up the price at 1s. per unit, with very slight changes, have, says *Industries and Iron*, commenced a rate-cutting war, with the view of securing one another's customers. The English Company has offered to a large club, which was consuming by the meter current to the value of £960 per annum, to provide them with better light for a lump sum

Digitized by Google

of £600 per annum, without employing any meter. So far both companies, although their charge is heavy, are able to supply current below the cost of gas, and for this reason electric lighting continues to gain ground in Madrid.

A French Trolley Line.—The third electric tramway on the overhead trolley system in France was "inaugurated" on December 17th. The line is three miles long, and runs along the bank of the Gironde from Bordeaux-Bouscat to Vigean, the gradients and curves being remarkably easy throughout. The line is provided with motor-cars carrying 40 passengers and weighing five tons, and with "trailers" carrying 50 passengers. Each motor car is provided with a single-reduction 15-H.P. Thomson-Houston motor, weighing, with gearing, just upon 1 ton. The ordinary speed is 7½ miles an hour. The installation is said to exhibit at one and the same time "the characteristics of American practice and the elegance and good taste of France."

Gas-Retort Carbon.—In the course of a Paper recently read before the German Gas Association, Dr. Hempel drew attention to the high price of large masses of retort graphite, a material useful in many ways nowadays, particularly in making electric light carbons and electrodes. Alluding to the fact that people are now going in on the largest scale for making caustic soda and chlorine by the direct electrolytic decomposition of common salt, and that for that they require large gas-carbon electrodes, which they cannot get, Dr. Hempel asked whether the retorts could not be so shaped as to yield graphite at once in large workable plates or slabs, and suggested that it ought to be easy to get thick copper or iron conductors embedded in the retort itself.

The Matabeles and the Telephone.—In describing the visit to England of Babjaan and Umsheti, two envoys of King Lobengula, a writer in the *Review of Reviews* relates this interesting incident:—"But the thing which completely astounded them was the telephone. They could conceive—though with difficulty—that it was possible for English witchcraft to make a machine which could talk English, even when those who talked were a mile from each other, but they could not understand the witchcraft which enabled the English to make the telephone speak Matabele. But that it did they could swear. They had been separated, and at the distance of a mile apart Babjaan had talked to Umsheti by means of this magic, and the machine spoke as pure Matabele as if it had been made in Africa."

A Long Telegraph Circuit.—On December 3rd, the President's message was transmitted direct from the New York Bureau of the United Press to San Diego, Cal., *viâ* the Postal, Canadian Pacific, and the Pacific Postal telegraph lines. There were twelve repeaters in the circuit, situated as follows:—Albany, 150 miles; Montreal, 343 miles; Sudbury, Ont., 444 miles; Fort William, Ont., 533 miles; Winnipeg, Man., 426 miles; Swift Current, N.W.T., 511 miles; Donald, B.C., 513 miles; Vancouver, B.C., 458 miles; Portland, Ore., 367 miles; Ashland, Ore., 316 miles; San Francisco, Cal., 402 miles; Los Angeles, Cal., 473 miles. San Diego is about 122 miles south of Los Angeles, which makes the total length of the circuit 5,080 miles. The message consisted of 5,211 words, and the time occupied in transmitting the same was three hours and forty-two minutes.

The Junior Engineering Society.—At the last meeting of this society, held at the Westminster Palace Hotel, Mr. Percy Waldram in the chair, a Paper was read by Mr. S. Cutler, jun., on "Coal Gas Manufacture, and Recent Improvements of the Plant employed therein." Commencing by showing how rapidly the demand for gas had increased since its introduction, the author proceeded to briefly describe the usual processes of gas manufacture, passing on to a detailed account of the recent improvements which had been adopted. The inclined system of retorts to obtain automatic charging and drawing; the latest forms of condensers and purifiers; compressed air, hydraulic, and rope-power machinery for working horizontal retorts; water-seal valves; water gas plant; and other features being dealt with. In conclusion, the cost of manufacture; by-products; the future of gas considered in respect to electricity; and gas employed as a heating agent were touched upon. A discussion followed the reading of the Paper.

Telegraphic Addresses.—In reply to Mr. Henniker Heaton, Mr. A. Morley stated in the House of Commons on Wednesday evening that as telegrams were urgent communications it was the universal rule throughout the Telegraph Union to require that the address should contain all the particulars necessary to insure delivery, so that no delay might be incurred in inquiries or references to directories or other books. Although this was the rule, the Department did take some trouble to deliver telegrams the addresses of which appeared to be defective by accident and not by design; but it would be contrary to the interests of the public that it should allow its officers' time to be spent in procuring the delivery of telegrams which were systematically sent with insufficient addresses. Not only would the telegrams in question be delayed, but telegrams bearing sufficient addresses would also be delayed, and the whole character of the service would be altered for the worse. The case of telegrams was not analogous to that of letters.

Long-Distance Transmission of Power.—At Jalisco, Mexico, a long-distance electric power plant is in operation for street lighting at Quadalajara. The generation station is on the Rio Grande river at a point 17 miles distant, and where there is abundant water power. Three 500-H.P. horizontal turbines have been installed to drive five alternating dynamos, four for arc and one for incandescent lighting. As a safeguard against floods the turbines are placed 16ft. above the bed of the river. A grooved pulley is carried at both ends of the shaft of each turbine and connects by rope transmission with countershafting on the floor above. The rope used is laid in plumbago and tallow and runs at the rate of 6,594ft. per minute. The pressure is increased from 1,000 volts to 5,000 volts by means of a set of 10 transformers, and at the lighting station in Quadalajara it is again reduced in the same manner. Lightning is apt to cause trouble in that locality, so the poles are all of iron and provided with a pointed arrester extended 3ft. above the top of the pole.

The Telephone at the Antipodes.—So rapidly is science extending its conquests, says the *Melbourne Argus*, that many sheep stations, which were formerly only connected by the dreary tramp of the sundowner are now linked together by the telephone. So long as a squatter keeps his telephone on his own property he is quite within his rights; but if his wires cross a public road he renders himself amenable to the law, which forbids a private person to erect a telephone or telegraph, the monopoly being reserved for the Government. The Colonial Postmaster-General does not wish to prohibit telephones under such circumstances, and he has, therefore, had regulations prepared, which have been passed by the Governor in Council, charging a licence fee of £1 per mile per annum for the first four miles, and after that 10s. per mile; the fee, however, in no case to exceed £7 per annum. The height at which the wire must be carried across roads is specified, and it is also provided that in no case shall a fee be charged or accepted for the use of the line.

Electricity and Windmills.—The Netherlands Society for the Promotion of Industry offer a gold medal and £30 for the best Paper on the production of electricity by windmills, its storage, transmission, and utilisation. The following points in particular should be attended to:—1. What is the average energy a common windmill is able to produce per day of 24 hours in combination with an electric accumulator; what would be the installation most suitable to this effect, and what would be the cost of one horse-power hour? 2. Is it possible, from an economical point of view, to apply the new aerial motors on an extensive scale for the accumulation and the utilisation of this energy? If so, what mechanical appliances would be required for this purpose? The project of a supposed application of the system, by which a factory is provided with light and power, is wanted as an illustration. Answers must be sent before July 1, 1894, with the author's name, in a closed envelope, to the general secretary of the Society, F. W. Van Eeden, at Haarlem, Holland.

Obituary.—The death occurred on the 20th inst. of Sir George Berkley, a past-President of the Institution of Civil Engineers, who was made a K.C.M.G. in June last "for services rendered as consulting engineer to the Government of Natal

Digitized by Google

and in connection with other colonies."——The death of Mr. Stephen Wilcox, the well-known mechanical engineer, vice-President of the Babcock and Wilcox Company, took place in Brooklyn on the 27th ult., at the age of 63 years. Mr. Wilcox was very well known as a mechanic and engineer, his life having been devoted to mechanical and engineering work. In 1856 Mr. Wilcox devised a boiler which was the prototype of the present inclined water-tube boiler so largely used in generating stations, and since that time has been actively engaged in perfecting and developing that and kindred matters pertaining to steam plants. With Mr. Babcock he organised and built up the New York Safety Steam Power Company, a business which was disposed of by them about ten years ago, when the boiler business became so extensive as to demand all their time. Recently Mr. Wilcox had been making some experiments in the direction of a marine boiler, and was engaged in that work especially at the time of his death.

The Post-Office and the National Telephone Company.—Attention is rightly being called to the curious difference in the attitude of the past and present Postmasters-General on the telephone question. Sir James Fergusson, speaking in March last year, stated that, supposing local authorities were willing to take telephone contracts themselves, he did not see anything contrary to Government policy in such a proposal. A Treasury minute quoted by Sir James Fergusson on that occasion declared that the Government would comply with the reasonable demand of any town or district for telephonic facilities. Notwithstanding this very definite expression of opinion from his predecessor, Mr. Arnold Morley declines to act up to it, and in the case of Glasgow, for instance, has refused the facilities which Sir James Fergusson says the townspeople are perfectly justified in asking for. Attention will be drawn to this anomalous state of things in the House of Commons early next year. Mr. A. C. Morton will set down a motion declaring that the Post Office telephone contract, and all that relates thereto, shall be referred to a select committee of the House, so that the local authorities of the United Kingdom shall have an opportunity of stating their views on the question.

The Supply of Electric Poles in America.—Telegraph and telephone companies in some parts of America, it is said, are becoming not a little alarmed, says the *Electrical Engineer*, of New York, at the rapid depletion of material for poles. Formerly, when poles carried but one or two lines of wire, very small ones could be used, but now nothing less than a pole 32ft. high and 8in. through at the top end is of any good, and the supply is getting very limited. The rapid consumption by telephone lines of small poles and the thousands of new poles cut each year are two important factors that the telegraph people have to face. The only pole worth setting that grows in Maine is a cedar, and these if well set and of good size will last a long time. Some have been in use over forty years. The only trouble with a cedar is its brittleness in frosty weather. The supply of cedar has become so short that of late years a large number of chestnut from Massachusetts have been used. They are costly, but are very handsome and durable. Some idea of the cost of poles can be had when it is stated that the cost of wire and labour is equalled by the cost of the poles alone. A good chestnut 32ft. long is worth from $3 to $4. What will be used for poles in the future is an important question. With such an increased demand for chestnut poles they are likewise being cut off at half their growth, and they, too, will be available but a few years.

Electro-Biological Research.—By the generosity of M. G. Solvay, says *Nature*, two important institutes have been established at Brussels, namely, a University Institute of Physiology, and an institute specially designed for carrying on electro-biological researches. In May last M. Solvay presented the town with a sum of two hundred thousand francs for the erection and equipment of the University building, stipulating only that the University should provide courses in physiological chemistry, and medical physics relating to the connection between physiology and electricity. This condition was laid down with the object of improving the instruction at the University, and developing the spirit of investigation in the minds of students, thus giving them the ability to carry on physiological researches independently in a special laboratory. For students thus trained, and desiring to apply their knowledge to research of a special kind, the Solvay Institute has been established. At the inauguration of this institute, on December 14th, M. Solvay delivered an address on the *rôle* of electricity in the phenomena of life. He remarked that his conviction was that the phenomena of life could probably be explained by the action of physical forces, and that, among these forces, electricity played an important part. It was to obtain evidence on this point, by the observation and study of facts, that M. Solvay was led to found the institute that bears his name.

Engineering at Cambridge.—*The Times* of Christmas Day contained the following letter from Prof. Ewing :—

Sir : Two years ago, on Christmas Day, you were good enough to appeal in a leading article for funds with which to create an engineering laboratory at Cambridge. You pointed out what the University was doing to promote the teaching of engineering, by the establishment—then contemplated and now an accomplished fact—of a tripos in the subject, and by its grant of a site for a laboratory. In the depleted state of the University chest nothing more than these evidences of goodwill could be expected, and you added—" Here, then, is an opportunity for someone willing to connect his name with the supply of a great educational need. A sum of £20,000 is required to put the whole thing upon a sound basis, and in a country containing so many wealthy men it does not seem extravagant to hope that someone may be found willing to imitate the example of the benefactors who in ancient times endowed the colleges." The millionaire whom you invited to come forward did not appear ; but instead of that a subscription list was opened. The Chancellor, the Duke of Devonshire, subscribed £1,000. Thanks to the liberality of resident and non-resident members of the Senate, and also of many prominent engineers and others interested in this new development of the University's work, a sum of close on £5,000 has been raised, and, in addition, a large number of valuable gifts of machinery and instruments have been received. The new tripos has attracted so many students (77 are now in attendance) that the University, recognising the urgency of the case for a laboratory, has strained its resources so far as to supplement the donations by a grant of £1,000. These moneys are at present being spent in building as much of the laboratory as they will pay for, and next term we shall be in occupation of some of the rooms. But a large part of the plan is put off for lack of funds, and, what is of more immediate concern, we cannot provide some very necessary plant and fittings until further subscriptions come in. Those who read, and especially those who responded to the appeal of your article, may be interested to know these particulars of what has been done. The need for help remains, and I do not doubt that there are many old Cambridge men, not yet subscribers, who would give if only they knew how much it is wanted.

The Intrusion of Physical Ideas into the Development of Pure Mathematics.—Writing in the *Physical Review* for September-October on Mr. Oliver Heaviside's recently-published collected papers, Mr. Alexander Macfarlane makes the following pithy remarks about the value of using settled physical ideas in the development of mathematical analysis :—

It will be, perhaps, in the recollection of some readers that Professor Sylvester, a few years since, in the course of his learned paper on Bipotential, poked fun at Professor Maxwell for having, in his investigation of the conjugate properties possessed by complete spherical-surface harmonics, made use of Green's theorem concerning the mutual energy of two electrified systems. He said (in effect, for the quotation is from memory) that one might as well prove the rule of three by the laws of hydrostatics, or something similar to that. In the second edition of his treatise Professor Maxwell made some remarks . . . to the effect that, although name involving physical ideas are given to certain quantities, yet, as the reasoning is purely mathematical, the physicist has a right to assist himself by the physical ideas. Certainly ; but there is much more in it than that. We may, indeed, get rid of the principle of energy, and treat the matter as a question of the properties of quadratic functions : a method which may commend itself to the pure mathematician. But, by the use of the principle of energy, and assisted by the physical ideas involved, we are enabled to go straight to the mark at once and avoid the unnecessary complexities connected with the use of the special functions in question which may be so great as to wholly prevent the recognition of the properties which, through the principle of energy, are necessitated. It seems to me that we may go even further, and hold that mathematical analysis should be based, not on arbitrary laws, but on physical principles. Certain it is that the great developments of analysis have been due to an infusion of physical ideas and principles.

The difficulty, however, seems to be about the value of the line of argument. If one only wishes to arrive at a result, and is not particular as to the strictness of the premises or of the logical sequence of the steps, then the intrusion of physical ideas to get mathematical results is all very well. But if the object is to preserve a well-defined line of argument, which may be easily re-traced, it is putting the cart before the horse to employ concrete generalisations in purely abstract research.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 136.)

Measurements of Work and Power.—Even at this early stage it must be evident to the reader that it will be necessary to employ some method of determining the load, power, and work done by an engine or complete plant, with a view to calculating its efficiency, rateable power capacity, load factor, &c. We will now consider some of the principles of these measurements, taking firstly the measurement of work. Work is considered in two aspects in engineering:—(1) as the consequence of power exerted for any time; (2) as the result of force exerted through any distance. The first is represented in Fig. 2 (see *ante* p. 159), where the horizontal axis measures the interval of time, and the vertical ordinate at any point on the axis of time gives the value of the power at that moment of time. In curve (*c*) the engine is working at a constant rate, so that the work it does is represented by the area of the rectangle O H, H J. In curve (*a*) the rate is never quite constant; but if we consider a very brief interval it may be taken as being approximately constant, the error being reduced in proportion to the length of the interval, so that a thin vertical strip of the curve (*a*) gives the work done in the brief time represented by the base of that strip; therefore the whole area of the curve A, B, C, D, E, F, T, O, A will give the total work done. We may ascertain this area by means of a planimeter, or by drawing the curve on uniformly thick paper, cutting it out and weighing it in a delicate balance against the weight of the square piece of paper on which it was drawn; or by means of Simpson's rule. This rule gives

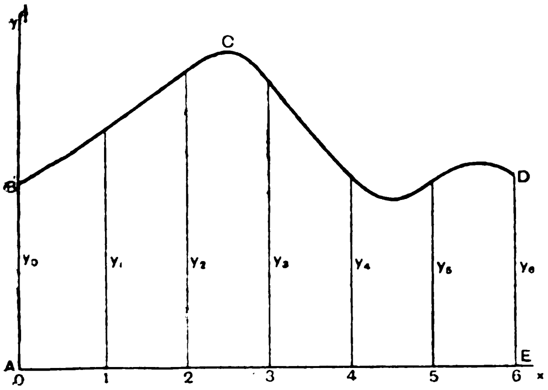

FIG. 3.

a result as nearly accurate as may be desired, according to the number of observations made. In Fig. 3 let it be required to find the area of the curve A, B, C, D, E, A, the ordinates and abscissæ of which are on known scales. Divide the area into n strips by means of $(n+1)$ equi-distant ordinates, as shown; and number these ordinates $y_0, y_1, y_2, \ldots y_n$. Let the total length of the base be x. We now treat each strip as if it were a true trapezoid, in which case the area of the first strip is—

$$a_1 = \frac{x}{n} \cdot \frac{y_0 + y_1}{2},$$

and of the last strip—

$$a_n = \frac{x}{n} \cdot \frac{y_{(n-1)} + y_n}{2}.$$

While the total area is

$$\text{area} = a_1 + a_2 + \ldots a_n = \frac{x}{n}\left(\frac{y_0 + y_1}{2} + \frac{y_1 + y_2}{2} + \ldots \frac{y_{(n-1)} + y_n}{2}\right) = \frac{x}{n}\left(\frac{y_0 + y_n}{2} + y_1 + y_2 + \ldots y_{(n-1)}\right). \quad (30)$$

The error made in treating each strip as a trapezoid is proportionate to the width of the strip and to the rate of curvature. By taking a large number of strips it may be made very small. Where there are points of contrary curvature in the curve the errors due to one set of strips will be more or less cancelled by those due to the other set; as, for example, in the strips between 4 and 5, and 5 and 6, in the first of which the estimated area is too large, and in the second too small. Usually, where the curves are not complicated by numerous and rapid variations, we take n equal to 10. If we apply this rule to Fig. 2 we may obtain the work done by the station or by any one machine; to complete the calculation, it being only necessary to find the number of units of work represented by unit area. This latter may be found by multiplying the number of units of power in the unit length of ordinate (or the scale of power) by the number of units of time in the unit length of abscissa (or the scale of time); the product multiplied by the area gives the work done. An equally simple method of determining the area of a curve which is used in finding the area of the diagram of work done in the cylinder of an engine consists in taking the average of the middle ordinates of all the strips, and multiplying this average by the base of the curve. In Fig. 3, if lines are drawn to represent the mid-ordinates of the strips (which may be scaled off), the average of these is the average

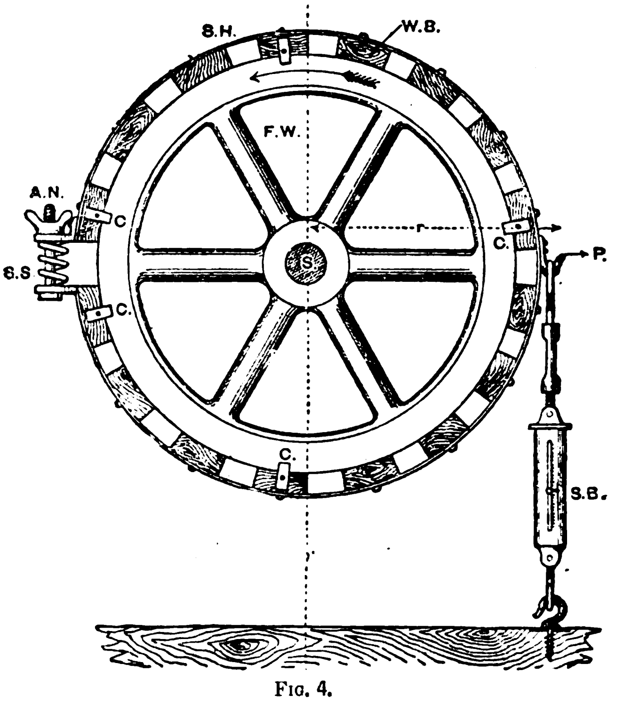

FIG. 4.

of the ordinates within a limit of error which depends on the number of strips taken. By the product of this average into the length of the base the area may be found, and the area, multiplied by the number of units of work in unit area, gives the measure of the work done.

If the axis x in Fig. 3 represents the distance in feet through which a variable force is exerted, the force being everywhere represented by the ordinate y, it is evident that the area is a diagram of work done by that varying force. Such a diagram of work can be automatically drawn on a sheet of paper by a pencil, if the vertical motion of the pencil and its height above a datum line are determined by the force, and if the paper receives a horizontal motion proportional to that with which the force is exerted on the moving body. An instrument for this purpose is called an *indicator*, the diagram obtained by means of it is called an *indicator diagram*, and the measure of the work determined in this way is called the *indicated work*. Indicated horse-power (I.H.P.) is the power based upon measurements of indicated work and speed. It will be convenient to study the indicator in relation to the special engines for which it is designed.

Dynamometry.—For the purpose of measuring the power which is taken from a pulley, or transmitted through a shaft or belt, we have recourse to some form of dynamometer. The derivation of the term dynamometer would seem to indicate that this is an instrument for the measurement of force; but, strictly speaking, it is only indirectly used to indicate force,

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

and its direct purpose is to measure work or power. It is most commonly used for the purpose of measuring power, which is then known as brake horse-power, from the fact that dynamometers are frequently used which act as brakes upon the engine. There are two classes of dynamometers, absorption dynamometers, or brakes, and transmission dynamometers. The former measure only the power which they are allowed to absorb and waste, the latter measure the power which passes through them to some machine, and only waste power in proportion to their imperfection of action. Brakes or absorption dynamometers are usually built of blocks or bands of some comparatively soft and rough material, these being pressed against the rim of the pulley where the power is to be measured. A simple form is the Prony brake, which is represented in a modern form in Fig. 4. A number of wooden blocks, WB, are secured to a flexible band or strap, SH, and fitted round the pulley or flywheel, FW, in the manner shown, being held in place by means of a few clamps, C, which prevent the blocks slipping off sideways, but do not prevent the pulley from turning. The blocks first fit the pulley loosely, but can be tightened up as required by means of the adjustable nut, AN, and the spiral spring, SS. At one end of a horizontal diameter of the pulley, and at a radius, r, there is a hook, P, to which a strong spring balance may be attached. This spring balance is shown at SB, and is coupled up through a tightening nut which alters the length of the coupling rod. The engine is set in motion, care having been taken to place the brake so that the motion will be away from the spring balance and will tend to stretch it. Then the blocks are gradually tightened up until the engine is running at its proper speed. Next, the nut is tightened up so as to bring the hook, P, back again to the horizontal level with the centre of the shaft, S, and care is taken to see that the coupling rod of the spring balance is quite vertical. Let the force in pounds on the spring balance be now read; let it be W lbs. At the same time that the reading of W is taken, all adjustments being in order, the speed of the pulley must be noted on a speed counter placed against the shaft, S. Let this be N revolutions per minute. Evidently the force, W, balances, at the radius, r, the frictional resistance of the brake blocks which acts at the radius of the pulley, say R; so that—

$$W : \text{Friction} :: R : r.$$

Now if the force of friction is multiplied by the velocity of the rim, the product is the power expended. Whence,

$$\text{Power expended} = \frac{W.r}{R} \times \frac{2\pi R.N}{60} = \frac{2\pi W.r.N.}{60} \quad . \quad (31)$$

$$\text{And,} \qquad H.P. = \frac{2\pi W.r.N.}{33{,}000} \quad . \; . \; . \; . \; . \; . \; . \; . \quad (32)$$

With such measurements, however, there are innumerable difficulties. In the first place, the measurement is made on an engine which cannot be permitted to do any useful work during the test; in the second place, the engine is often placed under abnormal conditions, differing widely from the conditions of practical running; in the third place, it is difficult to take accurate readings on account of the great heat and vibration produced in the brake. In regard to the first, it may be said that absorption dynamometers must be abandoned if the engine cannot be freed for a time long enough for the test; of the second, it may be said that care should be taken that the internal conditions of the engine, the speed, &c., are identical with those for which the engine is built, and that the brake does not impose conditions on the engine which will differ, either prejudicially or advantageously, from those of ordinary running. A glance at Fig. 4 will show that the brake there shown will supply a force at the point P, which will set up pressures on the engine bearings quite different from those occurring when the same engine is driving a belt. The effort should be made to absolutely imitate the conditions of practice, for then only can reliable results be obtained. As regards the heating and vibration: the first is usually got rid of by a copious stream of soapy water directed between the blocks and the pulley face; and the second is often diminished by means of a dash-pot on the brake strap. Other forms of brake dynamometers are constructed, some of which supply friction by means of a length of leather belt thrown over the pulley face and held in contact with it by means of weights or spring balances.

Transmission dynamometers may be divided into two classes: those which measure power transmitted by means of a belt or set of ropes, and those which measure power in a shaft. Of the first class, we may notice one form which has been used largely in dynamo tests—the Alteneck dynamometer. The general arrangement of this instrument is shown in Fig. 5. Power is being transmitted from the pulley A to the pulley B, through a link leather belt, C, which passes, both at the upper and lower parts, through the dynamometer. The instrument consists of a rectangular framework, D, with idle pulleys pivoted at the four corners, E, F, G, H, and two other idle pulleys, I and M, also pivoted to the frame. In addition, there is a movable pulley, P, attached to a lever which is pivoted at the centre of M. The tight side of the belt tends to lift this pulley, P, while the slack side presses downwards upon it. The motion of the lever is controlled by a dash-pot. Attached to the lever at the centre of P there are two vertical rods, R and Y. The rod, R, terminates at its lower end in a spiral spring, the tension of which is adjusted by the handle, T, and indicated on the scale, Z. The rod, Y, terminates at its upper end in a small lever, pivoted at O. This lever is weighted on its further side, and is provided with a pointer which travels over a scale on which there is a zero mark, m. The instrument having been fixed into position, the handle, T, will next be turned so as to bring the pointer of the top lever to the mark,

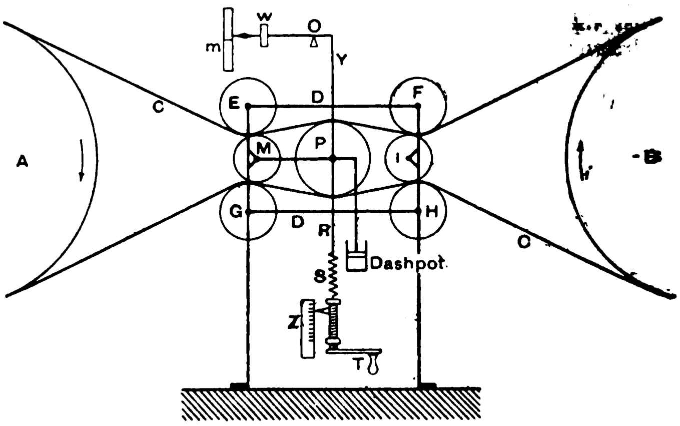

Fig. 5.

m. The reading on the scale, Z, is noted. The engine will now be started, the motion being such as to put the lower part of the belt into greatest tension. Instantly the pointer will fall below the mark, m, on account of the pulley, P, being lifted; but this must now be rectified by turning the handle, T, so as to increase the pull of the spring, S, until the pointer again stands at m. The reading on the scale, Z, is again noted, and the former reading subtracted from it. Simultaneously with these observations, the velocity of the belt must be observed, by measurement of the speed of either of the pulleys, A or B, the diameter of the pulley having previously been accurately measured. Let D be this diameter in feet, N the speed of the pulley in revolutions per minute, W the difference between the two readings on the spring scale, Z, and k a constant which is marked on the instrument. Then,

$$H.P. = \frac{\pi D N W}{33{,}000\,k} \quad . \; . \; . \; . \; . \; . \quad (33)$$

The second class of transmission dynamometer is placed in a gap or break in a line of shafting, and forms a flexible shaft coupling, through which the power is transmitted by torsion and angular motion. These instruments are sometimes provided with recording apparatus, for marking the diagram of torque or the power diagram on a sheet of paper contained within them. They are, however, only applicable to small amounts of power. Further consideration of the dynamometer testing of engines is reserved for treatment in a more complete manner in a later section.

SOME APPLICATIONS OF ELECTRIC HEATING IN PHYSICAL LABORATORY PRACTICE.*

BY EDWARD L. NICHOLS.

It is strange that so little attention has been given by physicists to the advantages of electric heating in calorimetric and other similar work. Prof. Henry Crew † quite recently described "a new method of obtaining a constant temperature" in which a coil of wire is used to heat an air bath with admirable effect. It would seem that devices more or less closely related to the one due to his ingenuity must have occurred to others engaged in laboratory operations; but I recall no published account of such methods. The application of electric heating for temperature control has been in use in the physical laboratory of Cornell University for a considerable time, and it gives me pleasure to confirm Mr. Crew's statements as regards the excellent results which may be obtained by means of it.

It will be seen from what follows that the methods of procedure to be described differ from his chiefly in three particulars: (1) the use of naked wire, whereby the range of temperature attainable is much increased; (2) the absence of the ice bath, it having been found that remarkable constancy of temperature within a heated coil occurred, under almost all ordinary conditions of the surrounding space; (3) the measurement of temperatures by means of a calibrated coil of copper wire.

The method to be described consists in heating the body or apparatus in question by means of a spiral coil of uncovered wire surrounding it. The wire, which may be of German silver, is traversed by strong electric currents, and thus brought to a high temperature. The best material for this purpose is some metal of small temperature coefficient. It should be capable of withstanding high temperatures without melting. The method under consideration has been applied under my direction in a variety of laboratory experiments. I propose to describe several of these briefly for the purpose of illustrating its advantages.

I. The first of these experiments was suggested by a Paper read by Prof. William A. Rogers at the Cleveland meeting of the American Association for the Advancement of Science. He called attention in that Paper to the fact that thermometers when subjected to a fall of temperature frequently indicate apparent discontinuity in the curve of cooling, the mercury column falling stepwise, and in some cases even retracing its course in the tube. This observation having been verified in the case of several thermometers of the best manufacture, it seemed of interest to determine whether the phenomenon might not be due in part to some peculiarity in the law of the contraction of glass. The experiments were made by Mr. Ernest F. Nichols. Rods of glass were mounted upon the bed of a comparator. One end of the rod was fixed, and to the free end a mirror was attached in such a manner that the changes in the length of the rod would produce a motion of rotation. The image of a vertical scale set up at a distance of about three meters was observed by means of a reading telescope. In this way every change in the length of the rod was greatly magnified. The rod was surrounded by an open spiral coil of iron wire reaching from end to end. Sufficient current was sent through the wire to heat it, and this current, which was supplied by a storage battery, was kept constant until the movement of the image of the scale had ceased. The circuit was then broken, and the rod was allowed to cool. A curve of cooling was obtained by noting the movement of the image at frequent intervals until the rod had reached the temperature of the room again. Upon plotting this curve it was found that the discontinuities in the rate of cooling if present in the case of the specimen of glass tested were extremely small. The curves were not perfectly true, but the irregularities were so small as to make it uncertain whether they were not to be ascribed to errors of observation or to imperfections in the apparatus. Rods of aluminium and brass also showed slight irregularities. The outcome of the experiment, therefore, was a negative one; but that it was evident from the curves obtained that the phenomenon noticed in thermometers could not be ascribed altogether to the suspected peculiarity in the law of the cooling of glass. From the point of view of the present Paper, however, the experiment was of considerable interest. It made it evident that this means of heating is an advantageous one in the study of the linear dilation of rods of considerable length.

II. In the same year, 1891, the method was applied to a determination of the coefficient of expansion of a standard meter bar of brass. This experiment was carried on by Mr. Joseph Le Conte. For the purpose of determining the temperature of the bar, the same was wrapped from end to end with several turns of fine silk-covered copper wire. The resistance of this longitudinal coil, the temperature coefficient of which had been previously determined with a good deal of care, was measured by the fall of potential method, using a sensitive galvanometer, a single cell of battery, and a compensated standard made by combining German silver and copper. Thus the temperature of the bar was averaged for its entire length. This bar was mounted upon a comparator, and was surrounded by a coil of large uncovered German silver wire in the manner described in Experiment I. The length of the bar was measured by means of reading microscopes attached to the comparator. The bed of the instrument was protected from the radiation of the coil by means of a layer of asbestos paper. It was found by trial that the rise of temperature of the massive iron bed of the comparator was almost unappreciable, even when the coil was heated to a temperature of 50°C. In this experiment the measurements were taken with the circuit closed, the bar having been brought to the desired constant temperature by long-continued application of the current. It was found that any temperature within wide range could be reached by simple adjustment of the resistance of the circuit through which the heating current flowed, and that no troublesome fluctuations took place. The coefficient of the bar was found to be in close agreement with determinations for this metal by the best known methods. The method of measuring temperature by means of an integrating coil extending over the entire length of the bar was also found to be superior to any procedure involving the use of a mercury thermometer. How very difficult it is to place thermometers so as to obtain true indications of the temperature of a bar in process of being tested is well known to all who have attempted work of this description. The calibration of the coil of copper wire for temperature measurements showed that the temperature indicated by it represented very closely indeed the temperatures of the mass of metal which it surrounded.

III. An experiment illustrating this method of heating, in application to work of another character, is as follows:—It was desired to determine the effect of heating sugar solutions upon the rotation of the plane of polarisation. In the Soleil saccharimeter the tube containing the fluid, the rotational coefficient of which was to be determined, was surrounded by a coil of German silver wire precisely in the method already indicated. It was found possible in this way to bring about temperature changes within the entire range below the boiling point of the solution, and to maintain them during the measurement of the angle of rotation. The entire apparatus consisted simply of a German silver helix surrounding the brass tube of the saccharimeter, in series with suitable resistances, and a galvanometer for the measurement of current. Since the temperature itself could not be readily determined directly at the time of observation, a calibration test was made with the thermometer inserted in the liquid, the temperature being measured as a function of the current flowing through the coil. The relation between temperature and current having been ascertained once for all, it was therefore only necessary to note the readings of the galvanometer in order to find the temperature to which the measurement of the angle of rotation applied.

CONDENSERS FOR ELECTRIC-LIGHT PLANTS.*

A large number of steam engines in electric lighting plants are situated so that an adequate supply of water can easily be had for condensation, but are at the present time non-condensing, labouring under a back pressure of 14·7 pounds due to exhausting against the atmosphere. The value of a vacuum to an engine under normal conditions is at a low estimate equal to 25 per cent. of the power developed by the engine running non-condensing. This means that, by the use of a condenser, the coal consumption can be reduced one-quarter to one-fifth with the same production of light, or the number of lights may be increased a fifth without burning more fuel.

With electric light and power companies, the cost of fuel is the great expense. The cost of the light is dependent primarily upon the cost of the coal, and any increased economy of the boilers or engines, improved belt transmission or dynamo efficiency directly affects the profits in nearly like proportions.

Upon changing an engine from non-condensing to condensing it is found that the boiler pressure in many cases may be lowered 15lb. to 20lb. with nearly as high results. Doing this often lengthens the life of the boilers considerably, and is very desirable to such as have had long service. When steam plants are located near dwellings, the noise of escaping exhaust steam is sometimes found to be annoying. This objectionable feature may be entirely relieved by the application of a condenser. Several engines may be exhausted into one condenser, and a vacuum maintained on all or part of them at a time.

The exhaust pipes from the engines lead to an exhaust trunk to which the condenser is attached. When an engine is stopped, it is shut off from the exhaust trunk by a gate valve in its exhaust

* Abstract from the *Electrical World* of New York.

Digitized by Google

pipe. In large plants it is well to divide the engines into groups, and use two or more condensers, putting those engines which have about the same time of running in the same group. At stations where the water supply is distant, inexpensive means can often be devised whereby the water can be reached. An excellent method is to lay a conduit, connecting the water supply with a well in the vicinity of the engines. From this well the water is readily taken by the condenser if the lift is under 20ft. Where the lift is greater, it is practical to lower the condenser by placing it in a pit. A cheap and serviceable conduit can be constructed of sewer pipe laid level, and at such a depth that a flow of water into the well is assured. The quantity of water needed to properly condense the exhaust steam depends, of course, on its temperature. It may be stated that 1¼ to two gallons of water per minute are required fo every horse-power developed by the engine. The use of city water supply for condensation is not recommended, unless the cost is so low as to be merely nominal.

ON COPPER ELECTROLYSIS IN VACUO.*

BY WILLIAM GANNON.

The following research upon the electrolysis of copper sulphate *in vacuo* was commenced nearly two years ago, at the suggestion of Dr. Schuster, and the experiments were made in the Physical Laboratory of the Owens College.

The electrolysis of copper salts is interesting, not only theoretically as affording a verification of Faraday's Law of Electrolytes, but also practically on account of its constant use in the graduation of current-measuring instruments, such as tangent galvanometers and ammeters. It is known that copper sulphate in solution does not conform rigorously to the simple form in which Faraday's law is generally expressed. Gray,† who made a detailed examination of the electrolysis of copper sulphate, found that the weight of the deposit is very variable in neutral solutions for the same current and the same interval of time; and he also showed that, in solutions containing a little free sulphuric acid, this inconstancy was removed, but that the weight was a function of the temperature of the solution and of the current density at the cathode. His results with acid solutions are graphically represented by curves (partly reproduced at the end of this Paper), an inspection of which shows that the deposit is heavier the higher the current density and the lower the temperature. ("Current density" is defined as the ratio of the value of the current in amperes to the total immersed surface of the cathode plate.) A very possible explanation of this anomaly is furnished by the work of Gore‡ and Gray,§ who independently found that copper dissolves to a very appreciable, though variable, amount in solutions of copper sulphate.

The secondary chemical reactions which follow—chiefly the formation of basic salts—complicate the electrolysis. This corrosion of copper plates in the sulphate solution is much diminished if a little free sulphuric acid is present, with the result that the electrolysis of acid solutions yields more consistent results than are obtainable with nearly neutral solutions. Now, Schuster‖ found that the loss in weight of copper plates in a solution of copper sulphate does not occur if the air be removed from the solution. It is, therefore, very probable that it is the oxygen of the air present in the solution that causes this chemical corrosion; and hence it was of interest to examine if any difference could be found between the weights of the deposits of two copper voltameters, one of which would be placed *in vacuo*. Schuster and Crossley¶ showed that the silver deposit is slightly greater *in vacuo* than in air; and the experiments tabulated in this Paper point out, with certain limitations, a similar result.

The results of my experiments may be briefly summarised:—

1. With two copper voltameters containing freshly-made neutral solution of copper sulphate, one of which is under reduced pressure, the copper deposit in the partial vacuum is higher (for the same current, current density, and temperature) than the deposit under the atmospheric pressure; but the percentage difference is not constant.

2. If a little free sulphuric acid be added to the air solution, the percentage difference is more constant and higher than in 1.

3. The addition of acid to both voltameters causes the percentage difference to be constant within experimental errors. The experiments conducted under this condition show that—

i. For current densities above 0·01 ampere per square centimetre of active cathode there is no practical difference between the two deposits.

ii. For current densities below 0·01 ampere per square centimetre the vacuum deposit is very appreciably higher than the air deposit.

iii. A curve drawn representing the deposits obtained *in vacuo* at different current densities is more regular than the air curves, and for densities below 0·01 ampere per square centimetre is approximately a straight line.

NOTE ON THE ACTION OF COPPER SULPHATE AND SULPURIC ACID ON METALLIC COPPER.*

BY PROF. ARTHUR SCHUSTER, F.R.S.

Mr. Gannon, in the foregoing Paper, refers to some unpublished experiments made by me a few years ago. These experiments were conducted for the purpose of satisfying myself that, as seemed *a priori* probable, the diminution of weight observed when metallic copper is exposed to the action of sulphuric acid or sulphate of copper is due to the presence of free oxygen in the liquid. Copper gauze was taken in order to deal with as large a surface as possible, and rolled up so as to fit into a piece of glass tubing. After the copper had been carefully washed, dried, and ignited in hydrogen, it was immersed in dilute sulphuric acid, the air above the acid was removed as far as possible, and the tube containing the gauze was then sealed hermetically. At the end of a fortnight a few tubes prepared in this way were opened and weighed after being subjected to exactly the same treatment as previous to immersion, that is to say, the copper was washed, dried, and ignited in hydrogen. The diminution in weight observed under these circumstances was insignificant. I cannot, unfortunately, now find the record of the actual weighings, but the quantities involved were about the same as in the next set of experiments. On January 26, 1891, four spirals of copper gauze were placed in a solution containing 20 per cent. of cupric sulphate, 5 or 10 per cent. by weight of sulphuric acid being added to the aqueous solution. The conditions thus approximated to the solutions which are used in the electrolysis of copper. The tubes were exhausted and sealed up: two of them were opened on February 2nd, and the two remaining ones on February 9th; the weighings were taken after drying and ignition in hydrogen. The results are shown in the accompanying table:—

Time of immersion.	Amount of sulphuric acid.	Weight before immersion.	Weight after immersion.
7 days	10 per cent.	17·512	17·510
7 „	5 „	14·357	14·356
14 „	10 „	14·267	14·265
14 „	5 „	18·471	18·468

It will be seen that the diminution in weight is quite insignificant compared to what takes place in the presence of air, and may be due to some remnant of oxygen left. The late Mr. Hoskyns Abrahall, however, suggested that it might also be due to the formation of copper sulphide; and this suggestion was supported by the fact that traces of sulphuretted hydrogen were given up when the copper, after immersion, was heated in hydrogen. The action would be represented by the formula

$$4\,Cu + SO_3 = CuS + 3\,CuO.$$

The above experiments prove that nearly the whole effect which is observed when copper is immersed in a solution of sulphate of copper or sulphuric acid is due to the presence of oxygen in the solution.

Electric Mail Cars in Ottawa.—A contract has been entered into, says the *Electrical Engineer*, of New York, between the Dominion Government and the Ottawa Electric Street Railway Company for the conveyance of the mails between the railway stations and the post office at Ottawa city. This service has hitherto been performed by mail wagons drawn by horses. The electric postal cars were made by the Ottawa Car Manufacturing Company, and equipped with 30-H.P. Westinghouse motors. The cars are 20ft. long, and are mounted on Brill trucks. The distance from the Post Office to the farthest railway station is a mile and a-quarter. The run is usually made in five or six minutes, while under the old system of horses the time occupied was never less than 20 minutes. The Postmaster-General and the Post Office officials are very much pleased with the change, and it is probable that a similar service will be put into operation in the other cities of the Dominion. Three cars are used in the service at Ottawa.

THE PROPOSED PACIFIC CABLE.

During the late tour of Mr. Mackenzie Bowell, the Canadian Minister of Trade and Commerce, through the Australian colonies, a memorandum, drawn up by Mr. Sandford Fleming, and containing definite proposals for the construction of a Pacific cable, was submitted by him to the Australian Governments. Copies of the memorandum have reached this country, and in *The Times* of Monday last there appeared an abstract of it, from which we take the following information. In our issue of May 6, 1892 (Vol. XXIX.) we discussed the various proposals at considerable length, and gave a map showing the proposed routes :—

Mr. Sandford Fleming's views were expressed at the Colonial Conference of 1887. His scheme embraces four alternative proposals for carrying a cable from Vancouver Island to Australia without landing on any territory which is not under British protection. By the first route the cable would run from Vancouver Island to Fanning Island, thence to the Fiji group. From Fiji it would run direct to New Zealand and thence to Australia. The distance by this route is 7,145 nautical miles, and the estimated cost of construction £1,678,000. By the second route the cable would run from Vancouver Island to an unoccupied island known as Necker Island, about 240 miles to the West of the Hawaiian group ; from Necker Island to Fiji, and thence to New Zealand and Australia. The distance by this route is also 7,145 nautical miles. The estimated cost of construction is £1,585,000. By the third route the cable would extend, as in No. 2, from Vancouver Island to Necker Island and thence to one of the eastern islands of the Gilbert group. From the Gilbert group two branches would extend, one to Queensland, touching at the Solomon Islands, one to New Zealand through Viti Levu, the southern island of the Fiji group. The distance by this route is 8,264 nautical miles. The estimated cost £1,825,000. The fourth route is identical with the third, except that it leaves out the branch to New Zealand. The distance is only 6,244 nautical miles, and the estimated expense £1,380,000.

As to the question of cost, Mr. Sandford Fleming proposes to meet it by constructing the cable as the joint property of the colonies concerned, and raising the capital required on their joint guarantee. He proposes to extinguish the subsidy of £32,400 paid by some of the Australian colonies to the Eastern Extension and payable until May, 1899, by purchasing an annuity of the required amount for those years, and thus adds a capital outlay of £145,000 to the sum required for the construction of the cable. If this arrangement be applied to No. 2 route, the capital required will be £1,745,000, and interest at 3 per cent. will bring the annual charge to £52,350. Mr. Standford Fleming's estimates as to working include the salaries of all officials, the cost of two steamers for current repairs, and the highest figure is £60,000. Besides working expenses it is proposed to establish a renewal fund of 2 per cent. on the cost of the cable, or £32,000 a year. The total estimated expense, including interest upon the capital, amounts, therefore, to £144,350 a year.

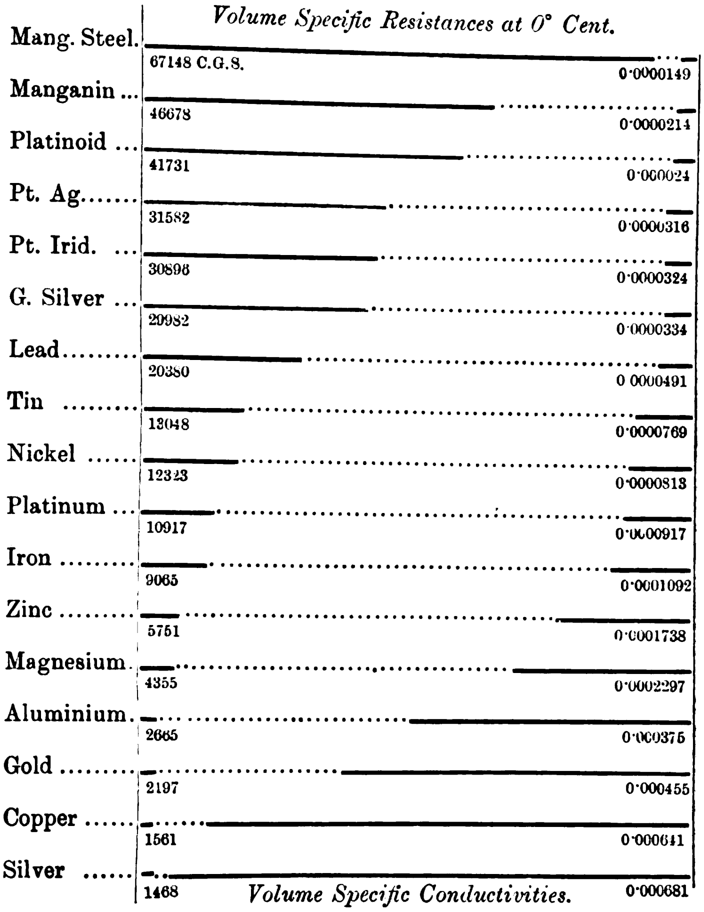
As to income, Mr. Sandford Fleming bases his calculation on the assumption that a Pacific cable may hope, when it is in complete working order, to take at least half of the messages now sent over the lines of the Eastern Extension Company. The number of words transmitted by that Company last year was 1,275,191. Dividing this into equal parts he takes 637,595 words as representing the probable business on which the Pacific cable would begin. But there is the increase of business to be taken into account. The normal increase under the old 9s. 4s. tariff was 14 per cent. per annum. The charge which it is proposed to make over the Pacific cable is 2s. a word. Thus messages would pass by that route from Australia to England for 3s. 3d. a word instead of 4s. 9d., which is the present charge. Putting aside, however, any estimate which might seem to be justified by these considerations, and basing his calculations on the assumption that business may stand still for three years and will afterwards continue only to increase at the normal high tariff rate of 14 per cent., Mr. Sandford Fleming works out the following table of the estimated earnings of the cable :—

Year.	Words per annum.	Earnings at 2s. per word.	Year.	Words per annum.	Earnings at 2s. per word.
1894	637,595	£63,759	1900	1,173,176	£117,318
1895	726,858	72,686	1901	1,262,439	126,244
1896	816,122	81,612	1902	1,351,703	135,170
1897	905,386	90,539	1903	1,440,967	144,097
1898	994,649	99,465	1904	1,530,230	153,023
1899	1,083,913	108,391			

It is scarcely to be supposed that the line would be in working order before 1896, and according to this estimate the business done in 1897 would be £90,539—that is to say, in the first year following the establishment of the line the business done might be expected to cover the whole of the working expenses and to give £30,539 for the renewal fund. After only seven years of working the business done would amount to £144,097, the scheme would be self-supporting, and the contributing Governments would be relieved from any further financial charge.

It is understood that a Conference will shortly be held in Canada for the purpose of discussing the scheme more fully, and if it be found to bear the examination of experts steps will be taken to procure the assent of all the Colonial Governments concerned.

RESISTANCES AND CONDUCTIVITIES OF METALS AND ALLOYS AT 0°C.



The length of the lines in this table is based upon the determinations of volume specific resistances by Profs. Dewar and Fleming. "Volume specific resistance" is defined as the resistance between opposite faces of a centimetre cube of the material in C.G.S. units. These values are marked under the lines, the value for manganese steel being 67148, and for silver 1468. If these numbers are divided by 100,000 the quotient is the resistance in *Ohms* of a wire of the material one metre long and one square millimetre in section. The lengths of the resistance lines of these two metals in the diagram are 67·1 millimetres and 1·5 millimetres respectively. The lengths of the lines representing "volume specific conductivities" are the reciprocals of the corresponding resistances. Wires of different metals, all of the same diameter, and of lengths equal to or multiples of the lengths of these conductivity lines, will all be of the same resistance. With wires of different metals, all of the same length and of the same resistance, the sectional areas must be proportional to the length of the resistance lines.
